SUBJECT: Soil Testing  
 Hopper Investigation  
 Belle River Coal Handling  
 Detroit Edison Company  
 Technical Specification, 10539-3-C-13  
 REFERENCE: Purchase Order No. AA2184

Dear Sir:

Enclosed herewith is the summary of laboratory testing conducted on soil samples received from the subject site, as authorized by the referenced purchase order. The laboratory testing was performed in accordance with your technical specification 10539-3-C-13 and included the following tests:

	<u>Pages</u>
30 Visual Classification and In-Situ Moistures	B-1, B-2, B-9
10 Atterberg Limits	B-3, B-4, B-5
30 Unconfined Compression	B-6 through B-28
2 In-Situ Moisture and Density	B-6, B-8
5 Mechanical Analysis	B-29, B-30

We appreciate the opportunity of serving you and trust that this work has been performed to your satisfaction.

Very truly yours,

U. W. STOLL AND ASSOCIATES

In-Kuin Kim, P.E.

# LAST PAGE

## **Test Applicability and Limitations:**

- The results are applicable only for the materials received at the laboratory and tested which may or may not be representative of the materials at the site.

## **Storage Policy:**

- Uncontaminated Material: All samples (or what is left) will be archived for a period of 3 months from the date received. Thereafter the samples will be discarded unless a written request for extended storage is received. A rate of \$1.00 per sample per day will be applied after the initial 3 month storage period.

- Contaminated Material: All samples (or what is left) will be archived for a period of 3 months from the date received. Thereafter, the samples will be returned to the project manager or his/her designated receiver unless a written request for extended storage is received. A rate of \$1.30 per sample per day will be applied after the initial 3 months storage.

Re: **DTE- Belle River (GLP-8017)**

Work Order: **20121752**

Dear Michael,

ALS Environmental received 3 samples on 18-Dec-2020 10:00 AM for the analyses presented in the following report.

The analytical data provided relates directly to the samples received by ALS Environmental - Holland and for only the analyses requested.

Sample results are compliant with industry accepted practices and Quality Control results achieved laboratory specifications. Any exceptions are noted in the Case Narrative, or noted with qualifiers in the report or QC batch information. Should this laboratory report need to be reproduced, it should be reproduced in full unless written approval has been obtained from ALS Environmental. Samples will be disposed in 30 days unless storage arrangements are made.

The total number of pages in this report is 21.

If you have any questions regarding this report, please feel free to contact me:

ADDRESS: 3352 128th Avenue, Holland, MI, USA  
PHONE: +1 (616) 399-6070 FAX: +1 (616) 399-6185

Sincerely,

A handwritten signature in black ink, appearing to read "Chad Whelton", is written over a light blue horizontal line.

Electronically approved by: Chad Whelton

**Project:** DTE- Belle River (GLP-8017)  
**Work Order:** 20121752

---

**Case Narrative**

Samples for the above noted Work Order were received on 12/18/2020. The attached "Sample Receipt Checklist" documents the status of custody seals, container integrity, preservation, and temperature compliance.

Samples were analyzed according to the analytical methodology previously transmitted in the "Work Order Acknowledgement". Methodologies are also documented in the "Analytical Result" section for each sample. Quality control results are listed in the "QC Report" section. Sample association for the reported quality control is located at the end of each batch summary. If applicable, results are appropriately qualified in the Analytical Result and QC Report sections. The "Qualifiers" section documents the various qualifiers, units, and acronyms utilized in reporting. A copy of the laboratory's scope of accreditation is available upon request.

With the following exceptions, all sample analyses achieved analytical criteria.

**Metals:**

No other deviations or anomalies were noted.

**Wet Chemistry:**

Batch R306912, Method SW9040C, Sample BAB-E (20121752-01B): pH is considered a "field test" and, as such, the recommended sample holding time expired prior to sample receipt.

Batch R306912, Method SW9040C, Sample BAB-W (20121752-02B): pH is considered a "field test" and, as such, the recommended sample holding time expired prior to sample receipt.

Batch R306912, Method SW9040C, Sample DB (20121752-03B): pH is considered a "field test" and, as such, the recommended sample holding time expired prior to sample receipt.

Batch R307145, Method SW9056A, Sample 20121752-03B MSD: The MSD recovery was outside of the control limit for Sulfate; however, the result in the parent sample is greater than 4x the spike amount. No qualification is required.

<u>Qualifier</u>	<u>Description</u>
*	Value exceeds Regulatory Limit
**	Estimated Value
a	Analyte is non-accredited
B	Analyte detected in the associated Method Blank above the Reporting Limit
E	Value above quantitation range
H	Analyzed outside of Holding Time
Hr	BOD/CBOD - Sample was reset outside Hold Time, value should be considered estimated.
J	Analyte is present at an estimated concentration between the MDL and Report Limit
ND	Not Detected at the Reporting Limit
O	Sample amount is > 4 times amount spiked
P	Dual Column results percent difference > 40%
R	RPD above laboratory control limit
S	Spike Recovery outside laboratory control limits
U	Analyzed but not detected above the MDL
X	Analyte was detected in the Method Blank between the MDL and Reporting Limit, sample results may exhibit background or reagent contamination at the observed level.

<u>Acronym</u>	<u>Description</u>
DUP	Method Duplicate
LCS	Laboratory Control Sample
LCSD	Laboratory Control Sample Duplicate
LOD	Limit of Detection (see MDL)
LOQ	Limit of Quantitation (see PQL)
MBLK	Method Blank
MDL	Method Detection Limit
MS	Matrix Spike
MSD	Matrix Spike Duplicate
PQL	Practical Quantitation Limit
RPD	Relative Percent Difference
TDL	Target Detection Limit
TNTC	Too Numerous To Count
A	APHA Standard Methods
D	ASTM
E	EPA
SW	SW-846 Update III

<u>Units Reported</u>	<u>Description</u>
°C	Degrees Celcius
mg/L	Milligrams per Liter
s.u.	Standard Units

Re: ALS Workorder: 2012397  
Project Name: DTE - Belle River  
Project Number: GLP-8017

Dear Mr. Coram:

Three water samples were received from Geosyntec Consultants, on 12/18/2020. The samples were scheduled for the following analyses:

Radium-226

Radium-228

The results for these analyses are contained in the enclosed reports.

The data contained in the following report have been reviewed and approved by the personnel listed below. In addition, ALS certifies that the analyses reported herein are true, complete and correct within the limits of the methods employed. Should this laboratory report need to be reproduced, it should be reproduced in full unless written approval has been obtained from ALS Environmental.

Thank you for your confidence in ALS Environmental. Should you have any questions, please call.

Sincerely,

ALS Environmental  
Julie Ellingson  
Project Manager

Accreditations: ALS Environmental – Fort Collins is accredited by the following accreditation bodies for various testing scopes in accordance with requirements of each accreditation body. All testing is performed under the laboratory management system, which is maintained to meet these requirement and regulations. Please contact the laboratory or accreditation body for the current scope testing parameters.

ALS Environmental – Fort Collins	
Accreditation Body	License or Certification Number
California (CA)	2926
Colorado (CO)	CO01099
Florida (FL)	E87914
Idaho (ID)	CO01099
Kansas (KS)	E-10381

Washington (WA)	C1280

40 CFR Part 136: All analyses for Clean Water Act samples are analyzed using the 40 CFR Part 136 specified method and include all the QC requirements.

## 2012397

### **Radium-228:**

The samples were analyzed for the presence of  $^{228}\text{Ra}$  by low background gas flow proportional counting of  $^{228}\text{Ac}$ , which is the ingrown progeny of  $^{228}\text{Ra}$ , according to the current revision of SOP 724.

All remaining acceptance criteria were met.

### **Radium-226:**

The samples were prepared and analyzed according to the current revision of SOP 783.

Sample 2012397-2 has a calculated yield as determined by ICP-AES above the 110% control limit at 132%. It is believed that there was native barium present in the sediment portion of the sample that was unaccounted for in the initial ICP aliquot. The result has been calculated conservatively, assuming a quantitative yield of 100%. This sample is identified with a "Y2" flag in the final reports, and the results are submitted without further qualification.

All remaining acceptance criteria were met.

13. Are all samples requiring no headspace (VOC, GRO, RSK/MEE, radon) free of bubbles > 6 mm in diameter?	<input checked="" type="checkbox"/> N/A	<input type="checkbox"/> YES	<input type="checkbox"/> NO
14. Were the samples shipped on ice?		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO
15. Were cooler temperatures measured at 0.1 - 6.0°C?	IR gun used: <input type="checkbox"/> #3 <input checked="" type="checkbox"/> #5	<input type="checkbox"/> Rad Only	<input checked="" type="checkbox"/> YES <input type="checkbox"/> NO

Cooler #: 1

Temperature (°C): 3.2

# of custody seals on cooler: 1

External mR/hr reading: 12

Background mR/hr reading: 9

Were external mR/hr readings ≤ two times background and within DOT acceptance criteria? (If no, see Form 008)

N/A  YES  NO

\* Please provide details below for 'NO' responses in gray boxes above - for 2 thru 5 & 7 thru 12, notify PM & continue w/ login.

11) Sample 2012397-1-2 had a pH of 4, 0.5mL of HNO3 was added to achieve a pH<2

All client bottle ID's vs ALS lab ID's double-checked by: RGA

Analyses	Result	Qual	Report Limit	Units	Dilution Factor	Date Analyzed
----------	--------	------	--------------	-------	-----------------	---------------

**Explanation of Qualifiers**

**Radiochemistry:**

- "Report Limit" is the MDC
- U or ND - Result is less than the sample specific MDC.
- Y1 - Chemical Yield is in control at 100-110%. Quantitative yield is assumed.
- Y2 - Chemical Yield outside default limits.
- W - DER is greater than Warning Limit of 1.42
- \* - Aliquot Basis is 'As Received' while the Report Basis is 'Dry Weight'.
- # - Aliquot Basis is 'Dry Weight' while the Report Basis is 'As Received'.
- G - Sample density differs by more than 15% of LCS density.
- D - DER is greater than Control Limit
- M - Requested MDC not met.
- M3 - The requested MDC was not met, but the reported activity is greater than the reported MDC.
- L - LCS Recovery below lower control limit.
- H - LCS Recovery above upper control limit.
- P - LCS, Matrix Spike Recovery within control limits.
- N - Matrix Spike Recovery outside control limits
- NC - Not Calculated for duplicate results less than 5 times MDC
- B - Analyte concentration greater than MDC.
- B3 - Analyte concentration greater than MDC but less than Requested MDC.

**Inorganics:**

- B - Result is less than the requested reporting limit but greater than the instrument method detection limit (MDL).
- U or ND - Indicates that the compound was analyzed for but not detected.
- E - The reported value is estimated because of the presence of interference. An explanatory note may be included in the narrative.
- M - Duplicate injection precision was not met.
- N - Spiked sample recovery not within control limits. A post spike is analyzed for all ICP analyses when the matrix spike and or spike duplicate fail and the native sample concentration is less than four times the spike added concentration.
- Z - Spiked recovery not within control limits. An explanatory note may be included in the narrative.
- \* - Duplicate analysis (relative percent difference) not within control limits.
- S - SAR value is estimated as one or more analytes used in the calculation were not detected above the detection limit.

**Organics:**

- U or ND - Indicates that the compound was analyzed for but not detected.
- B - Analyte is detected in the associated method blank as well as in the sample. It indicates probable blank contamination and warns the data user.
- E - Analyte concentration exceeds the upper level of the calibration range.
- J - Estimated value. The result is less than the reporting limit but greater than the instrument method detection limit (MDL).
- A - A tentatively identified compound is a suspected aldol-condensation product.
- X - The analyte was diluted below an accurate quantitation level.
- \* - The spike recovery is equal to or outside the control criteria used.
- + - The relative percent difference (RPD) equals or exceeds the control criteria.
- G - A pattern resembling gasoline was detected in this sample.
- D - A pattern resembling diesel was detected in this sample.
- M - A pattern resembling motor oil was detected in this sample.
- C - A pattern resembling crude oil was detected in this sample.
- 4 - A pattern resembling JP-4 was detected in this sample.
- 5 - A pattern resembling JP-5 was detected in this sample.
- H - Indicates that the fuel pattern was in the heavier end of the retention time window for the analyte of interest.
- L - Indicates that the fuel pattern was in the lighter end of the retention time window for the analyte of interest.
- Z - This flag indicates that a significant fraction of the reported result did not resemble the patterns of any of the following petroleum hydrocarbon products:
  - gasoline
  - JP-8
  - diesel
  - mineral spirits
  - motor oil
  - Stoddard solvent
  - bunker C

## Technical Memorandum

---

**Date:** November 24, 2021

**To:** Chris Scieszka, DTE Electric Company

**From:** Vince Buening, TRC  
Sarah Holmstrom, TRC  
Kristin Lowery, TRC

**Project No.:** 413591.0003.0000 Phase 1 Task 1

**Subject:** Groundwater Protection Standard Calculation – DTE Electric Company, Belle River Power Plant Diversion Basin

---

DTE Electric Company (DTE Electric) is pursuing an Alternate Liner Demonstration (ALD) for the Belle River Power Plant (BRPP) Diversion Basin (DB) coal combustion residual (CCR) unit. On November 12, 2020, the U.S. EPA published the Part B: Alternate Demonstration for Unlined Surface Impoundments amendments to the CCR Rule<sup>1</sup> (“Part B”) that allows a facility to prepare demonstration to request approval to operate an existing CCR surface impoundment with an alternate liner. Although the BRPP DB remains in detection monitoring, per § 257.71(d)(1)(ii)(C)(2), the ALD must demonstrate that, for each Appendix IV constituent, there is no reasonable probability that the peak groundwater concentration that may result from releases that occur over the active life of the CCR surface impoundment will exceed the groundwater protection standard (GWPS) at the waste boundary.

GWPSs are set as either specific regulatory standards identified in the CCR Rule or background groundwater concentrations, whichever is higher, for the Appendix IV constituents. Per the CCR Rule §257.95(h)<sup>2</sup>, the EPA maximum contaminant levels (MCLs) will be the GWPSs for those constituents that have established MCLs. For Appendix IV constituents that do not have established MCLs, the GWPSs are based upon the EPA Regional Screening Levels (RSLs). For constituents that have statistically derived background levels higher than the MCL and/or RSL, the GWPS becomes equal to the background level.

This memorandum presents the background statistical limits and GWPS derived for the Appendix IV parameters for the BRPP DB CCR unit using the aforementioned approach pursuant to §257.95(h). Per 40 CFR §257.94, a minimum of eight rounds of background sampling for the Appendix IV constituents were completed at the BRPP DB from August 2016 through September 2017, as part of initiating the

---

<sup>1</sup> On April 17, 2015, the U.S. EPA issued the Final Rule: Disposal of CCR from Electric Utilities (CCR Rule), 40 CFR 257, Subpart D, to regulate the disposal of CCR materials generated at coal-fired units.

<sup>2</sup> As amended per Phase One, Part One of the CCR Rule (83 FR 36435).

## Technical Memorandum

detection monitoring program. Since fluoride is in both the Appendix III and Appendix IV constituent lists, additional fluoride data were collected under the detection monitoring program subsequent to September 2017 and were also used in the development of the GWPS. All of the Appendix IV data used in this analysis (August 2016 through December 2020) and details on how the data were collected are included in the annual reports prepared in accordance with the CCR Rule through January 2021.

The background data for the BRPP DB were evaluated in accordance with the *Groundwater Statistical Evaluation Plan (Stats Plan)* (TRC, October 2017). Per the Stats Plan, the BRPP DB CCR unit uses an intra-well statistical approach. For intra-well methods, the background data set is comprised of the historical data established at each individual monitoring well, which accounts for natural spatial variability that occurs in background encountered across the site. Background data were evaluated utilizing ChemStat™ statistical software. ChemStat™ is a software tool that is commercially available for performing statistical evaluation consistent with procedures outlined in U.S. EPA's *Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities* (Unified Guidance; UG). Within the ChemStat™ statistical program (and the UG), tolerance limits were selected to perform the statistical calculation for background limits. Use of tolerance limits is a streamlined approach that offers adequate statistical power and is an acceptable approach under the CCR Rule. As such, upper tolerance limits (UTLs) were calculated for each of the CCR Appendix IV parameters, and, given that intra-well methods have been established for this site, a background UTL was calculated for each monitoring well and used to compare to the respective MCL or RSL. The following narrative describes the methods employed and the results obtained for the UTL calculations and the resulting GWPSs. The ChemStat™ output files are included as an attachment.

The set of background wells utilized for BRPP DB includes MW-16-05, MW-16-06, MW-16-07, MW-16-08, MW-16-10, and MW-16-11/A<sup>3</sup>. The background data evaluation included the following steps:

- Review of data quality checklists for the baseline/background data sets for CCR Appendix IV constituents;
- Graphical representation of the baseline data as time versus concentration (T v. C) by well/constituent pair;
- Outlier testing of individual data points that appear from the graphical representations as potential outliers;
- Evaluation of percentage of non-detects for each baseline/background well-constituent (w/c) pair;
- Distribution of the data;
- Calculation of the UTLs for each cumulative baseline/background data set; and
- Establishment of GWPS as the higher of the MCL/RSL or the UTL for each Appendix IV constituent.

The results of these evaluations are presented and discussed below.

---

<sup>3</sup> Monitoring well MW-16-11 was decommissioned and replaced by monitoring well MW-16-11A in May 2017 to repair a damaged casing. For the purposes of statistical evaluation, the data sets for the original and replacement well have been combined and referred to as "MW-16-11A"

## Technical Memorandum

### Data Quality

Data from each sampling round were evaluated for completeness, overall quality and usability, method-specified sample holding times, precision and accuracy, and potential sample contamination. The review was completed using the following quality control (QC) information which at a minimum included chain-of-custody forms, investigative sample results including blind field duplicates, and, as provided by the laboratory, method blanks, laboratory control spikes, laboratory duplicates. The data were found to be complete and usable for the purposes of the CCR monitoring program.

### Time versus Concentration Graphs

The time versus concentration (T v. C) graphs (Attachment A) indicated potential or suspect outliers for arsenic, chromium, cobalt, and lead at MW-16-07 on 8/3/2016, radium 226/228 at MW-16-11A on 8/2/2016, and chromium, cobalt, and lead at MW-16-11A on 9/22/2016. In addition, multiple sampling events were performed within a two to three-week timeframe during the background data collection in order to verify results and/or collect an adequate number of data points within the constraints of the limited CCR Rule implementation timeline. In order to maximize temporal independence within the background data set, several data points were removed from the MW-16-10 and MW-16-11A data sets as noted on Table 1. Data for the additional sampling events conducted in August 2017 for MW-16-10 were similar to the July and September results. Data for the additional sampling event conducted in June 2017 for MW-16-11A were similar to the May and July results. Thus, the June 2017 and August 2017 data were removed to avoid potential biasing of the two data sets for that time-frame.

While variations in results are present, the graphs show consistent baseline data and do not suggest that data sets, as a whole, likely have overall trending or seasonality. However, due to limitations on CCR Rule implementation timelines, the data sets, with the exception of fluoride, are of relatively short duration for making such observations regarding overall trending or seasonality.

### Outlier Testing

Outlier removal from the background data set is summarized in Table 1. Probability plots of data residuals (Attachment A) were used to further evaluate the potential outliers for MW-16-07 that were identified in the T v. C graphs. In general, probability plots of the data residuals for MW-16-07 show that arsenic, chromium, cobalt, and lead data collected on 8/3/2016 were from a different distribution than the remaining data. Prior to outlier removal, many of the parameters exhibited a non-normal distribution. Subsequent to outlier removal, the data sets for the majority of the parameters exhibited a normal distribution. As such, data collected from monitoring well MW-16-07 on 8/3/2016 were removed from the data set.

After the removal of the data collected on 6/6/2017 from the background data set for MW-16-11A, probability plots of the data residuals for MW-16-11A show the radium 226/228 data collected on 8/2/2016, and the chromium, cobalt, and lead data collected on 9/22/2016 were from a different distribution than the remaining data. Prior to outlier removal, many of the parameters exhibited a non-normal distribution. Subsequent to outlier removal, the data sets for the majority of the parameters exhibited a normal distribution. As such, these data points were removed from the data set.

## Technical Memorandum

### Distribution of the Data Sets

ChemStat™ was utilized to evaluate each data set for normality. If the skewness coefficient was calculated to be between negative one and one, then the data were assumed to be approximately normally distributed. If the skewness coefficient was calculated as greater than one (or less than negative one) then the calculation was performed on the natural log (Ln) of the data. If the Ln of the data still determined that the data appeared to be skewed, then the Shapiro-Wilk test of normality (Shapiro-Wilk) was performed. The Shapiro-Wilk statistic was calculated on both non-transformed data and the Ln-transformed data. If the Shapiro-Wilk statistic indicated that normal distributional assumptions were not valid, then the parameter was considered a candidate for non-parametric statistical evaluation. The data distributions are summarized in Table 2.

### Tolerance Limits

Table 2 presents the calculated UTLs for the background/baseline data sets. As discussed above, the BRPP DB CCR unit uses intra-well statistical methods; therefore, UTLs were calculated for each individual monitoring well. For normal and lognormal distributions, UTLs are calculated for 95 percent confidence using parametric methods. For nonnormal background datasets, a nonparametric UTL is utilized, resulting in the highest value from the background dataset as the UTL. The achieved confidence levels for nonparametric tolerance limits depend entirely on the number of background data points, which are shown in the ChemStat™ outputs. The intra-well tolerance limits for each parameter were compared to the MCL/RSL and the higher value was established as the GWPS for that well.

### Groundwater Protection Standards

The resulting GWPSs were established as the higher of the MCL/RSL or the UTL for each Appendix IV constituent at each monitoring well. The GWPSs are summarized in Table 3.

## TABLE OF CONTENTS

1. PURPOSE.....	3
2. ASSUMPTIONS.....	3
3. DARCY VELOCITY SOLUTION .....	3
4. TRAVEL TIME SOLUTION.....	4

## 1. PURPOSE

The purpose of this calculation package is to calculate the vertical Darcy velocity of the model lithology for input in Fate and Transport numerical model at the Belle River Power Plant Diversion Basin (DB). Following Darcy velocity calculation, the solution is used to calculate the time of travel from the DB to the Uppermost Aquifer.

## 2. ASSUMPTIONS

- Vertical flow is the dominant influence on contaminant transport; horizontal flow is not considered since a one-dimensional model was selected.
- Vertical hydraulic conductivity calculated in the laboratory using samples collected from borings is representative of subsurface conditions.

## 3. SOLUTION

The Darcy velocity ( $q$ ) through the model lithologies or layers is expressed in m/year =

$$= K(i) = K \left( \frac{H_1 - H_2}{l_1 - l_2} \right)$$

Where,

$K$  = vertical hydraulic conductivity (laboratory measured)

$i$  = vertical gradient

$H_1 - H_2$  = difference in hydraulic head between the DB water level and the uppermost aquifer potentiometric surface

$l_1 - l_2$  = distance in direction of flow

Thus:

$K$  = Geomean of Clay with Sand hydraulic conductivity value (data provided in Attachment 1) = Total  $2.15 \times 10^{-8}$  cm/s

$H_1$  = head at the bottom of DB = 579 ft

$H_2$  = Average water level elevation from monitoring wells (data provided in Attachment 2) = 575.16<sup>1</sup> ft

$l_1$  = Bottom of ash pond = 574 ft

$l_2$  = Average elevation of well screen midpoints = 449.88<sup>1</sup> ft

$q$  = **Darcy velocity in m/year (= cm/s \* 315360) =  $2.03 \times 10^{-4}$  m/year**

<sup>1</sup> Value is an average taken from all monitoring wells

#### 4. TRAVEL TIME SOLUTION

Travel time ( $T$ ) through the model lithology is expressed in years =

$$T = t / \left( \frac{K * i}{n} \right)$$

Where:

$t$  = minimum model thickness

$K$  = vertical hydraulic conductivity (laboratory measured)

$i$  = vertical gradient

$n$  = effective porosity

Thus:

$t$  = Minimum model thickness per EVS model = 35.36 m

$K$  = Hydraulic conductivity =  $2.15 \times 10^{-8}$  cm/s

$i$  = Calculated using variables in Section 3 = 0.03

$n$  = Average of porosity data from Clay with Sand layer, converted to effective porosity using Sara (1994) = 0.34

$T$  = **Travel time in years (= s / 31536000) = 59,105 years**

**Note:** Time travel is not an input to Pollute model. It has been calculated to provide time estimate for the travel of water molecule from the bottom of DB to top of uppermost aquifer.

Notes:

1. Kv = vertical hydraulic conductivity as determined by the analysis of field and laboratory data summarized in Table M-1
2. Analysis of vertical hydraulic conductivity includes data from long term tests updated on 8/20/2021
3. Kv of Clay with Sand selected for the calculation of the Darcy velocity as the higher and thus more conservative value of the two layers; POLLUTE only allows one input for Darcy velocity
4. CoHD = Coefficient of Hydrodynamic Dispersion
5. Effective Porosity determined by multiplying estimated porosity from field and lab data by 0.81, based on data provided by Sara, 1994

Figure 8.10 Chloride and potassium concentration versus depth in sample for model D (modified from Rowe et al., 1988).

variation in concentration with depth in the soil at the end of each test. The consistency of results demonstrates the power of the analytical model (program POLLUTE) and provides some con-

Figure 8.11 Chloride and potassium concentration versus depth in sample for model E (modified from Rowe et al., 1988).

fidence in the parameters  $D$  and  $\rho K_d$  for the clay and source fluids examined.

To provide an indication of parameter variation that might be expected for a given soil, a number of tests were duplicated. The diffusion coefficient,  $D$ , for chloride was deduced for each model and ranged between 0.018 and 0.02 m<sup>2</sup>/a with an average value of 0.019 m<sup>2</sup>/a. This small variation in  $D$  does not appear to be related to small differences in Darcy velocity, nor does it appear to be particularly related to the nature of the associated cation (see Table 8.3). Rather, the variability from 0.018 to 0.02 m<sup>2</sup>/a is seen as an indication of the level of repeatability that may be achieved for this type of test.

The application of an effective stress to the soil sample adopted in these tests is not an essential part of the proposed technique for determining the parameters  $D$  and  $K_d$ . Tests performed for the particular combination of clay and permeants considered herein gave similar results both with and without the application of the effective stress. However, for some combinations of clay and permeant, shrinkage of the clay may occur in the absence of a confining stress and this can give quite misleading results (e.g., see Quigley and Fernandez, 1989). For these clays, and for GCLs (see Chapter 12), tests should be performed at an effective stress similar to that anticipated in the field.

### 8.3.2 Pure diffusion tests

In many cases, it is not necessary to perform an advection-diffusion test. Under these circumstances, a simple diffusion test can be performed for boundary conditions shown in Figure 8.2. In this test, the soil sample is placed in a Plexiglass cylinder by trimming the sample to a size marginally greater than the specimen and then pressing the specimen into the cylinder, using a cutting shoe attached to the cylinder, to perform the final trim. This procedure is found to work well for many clays. However, it does not work well for clays with a significant stone content because the

## DB ExtendedRun

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## DB Darcy

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000407$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7    N = 20    SIG = 0    RNU = 2

### Calculated Concentrations at Selected Times and Depths

Time year	Depth m	Concentration mg/L
5	0.000E+00	1.000E+00
	5.560E-01	2.054E-01
	1.112E+00	1.109E-02

## DB CoHD High

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.02375 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.02375 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7    N = 20    SIG = 0    RNU = 2

### Calculated Concentrations at Selected Times and Depths

Time year	Depth m	Concentration mg/L

## DB CoHD Low

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.01425 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.01425 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

Time year	Depth m	Concentration mg/L

## DB ClayPoro High

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.45	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## DB ClayPoro Low

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.28	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## DB SandPoro High

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.45	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## DB SandPoro Low

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.2	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## DB ClayThick

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12.13 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## DB ClayThin

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	10.69 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	25.66 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## DB SandThick

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	26.82 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

Time year	Depth m	Concentration mg/L

## DB SandThin

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.000203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.12 m	20	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	24.65 m	50	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7    N = 20    SIG = 0    RNU = 2

### Calculated Concentrations at Selected Times and Depths

Time year	Depth m	Concentration mg/L

## 1. INTRODUCTION

This report has been prepared to provide the Alternate Liner Demonstration (ALD) of Belle River Power Plant Diversion Basin (DB), one of two coal combustion residuals (CCR) units at the site, in accordance with 40 CFR Part 257 as amended on November 12, 2020 (CCR Part B Rule). **Figure 1-1** provides the site location.

This report concludes that there is no reasonable probability that water from the DB will cause a release to the groundwater that will exceed the groundwater protection standards (GWPS) at the waste boundary over the projected active life of the CCR unit.

### 1.1 Background

DTE Electric Company (DTE) submitted the Alternate Liner Demonstration Application for the DB to the United States Environmental Protection Agency (USEPA) on November 30, 2020 [1] in accordance with the CCR Rule. Soon after, DTE started the field and laboratory investigation studies to meet the requirements of the CCR Rule.

One of the requirements of the CCR Rule is to conduct hydraulic conductivity testing using site-specific permeant liquid. The CCR Rule acknowledges that these tests may last a long time such that the operator of the CCR unit may need to submit an extension request for the laboratory testing program, and submit a preliminary ALD.

DTE submitted extension requests due to “analytical limitation” under separate covers, dated September 1, 2021 [2] and September 1, 2022 [3]. The extension requests detailed the compatibility testing program results through August 12, 2022. The USEPA has not yet responded to the extension requests.

The Part B Rule does not require the submittal of a preliminary ALD (PALD) by November 30, 2021 if an extension request is submitted in accordance with §257.71(d)(2)(ii)(A). However, DTE provided a PALD [4] out of an abundance of caution and with confidence in the performance of the liner system as a “place holder” to comply with the requirement to submit an ALD by November 30, 2021.

The PALD detailed the site investigation, conceptual site model, laboratory study, and fate and transport model concluding that there is no reasonable probability that water from the DB will cause a release to the groundwater that will exceed the GWPS at the waste boundary over the projected active life of the CCR unit. This ALD includes additional data analyzed subsequent to the submittal of the PALD, and confirms the appropriateness of the hydraulic conductivities used in the PALD fate and transport model.

## 1.2 Purpose

The purpose of this report is to provide the final ALD including the approach, analysis details, and results in accordance with the CCR Rule.

## 1.3 Report Organization

The remainder of this report is organized as follows:

- Section 2 – provides the field and laboratory investigation details, information on site geology/hydrogeology, and conceptual site model details.
- Section 3 – provides results of hydraulic conductivity testing, termination criteria details, chemistry testing of site-specific porewater, and discussion of results.
- Section 4 – provides analysis approach, details, GWPS, and evaluation of results as to whether the DB meets the ALD requirement of the CCR Rule.
- Section 5 – provides a summary of the report.
- Section 6 – provides certification.
- Section 7 – provides references.

## 1.4 Terms of Reference

This report was prepared by Mike Coram C.P.G., Clinton Carlson Ph.D., P.E., Jesse Varsho P.E., and reviewed by John Seymour, P.E. of Geosyntec Consultants of Michigan, Inc.(Geosyntec).

## 2. CHARACTERIZATION OF SITE HYDROGEOLOGY

The CCR Rule requires the following:

*§257.71(d)(ii)(A) Characterization of site hydrogeology. A characterization of the variability of site-specific soil and hydrogeology surrounding the surface impoundment that will control the rate and direction of contaminant transport from the impoundment. The owner or operator must provide all of the following as part of this line of evidence:*

*(1) Measurements of the hydraulic conductivity in the uppermost aquifer from all monitoring wells associated with the impoundment(s) and discussion of the methods used to obtain these measurements;*

*(2) Measurements of the variability in subsurface soil characteristics collected from around the perimeter of the CCR surface impoundment to identify regions of substantially higher conductivity;*

*(3) Documentation that all sampling methods used are in line with recognized and generally accepted practices that can provide data at a spatial resolution necessary to adequately characterize the variability of subsurface conditions that will control contaminant transport;*

*(4) Explanation of how the specific number and location of samples collected are sufficient to capture subsurface variability if:*

*(i) Samples are advanced to a depth less than the top of the groundwater table or 20 ft beneath the bottom of the nearest water body, whichever is greater, and/or*

*(ii) Samples are spaced further apart than 200 ft around the impoundment perimeter;*

*(5) A narrative description of site geological history; and*

*(6) Conceptual site models with cross-sectional depictions of the site environmental sequence stratigraphy that include, at a minimum:*

*(i) The relative location of the impoundment with depth of ponded water noted;*

*(ii) Monitoring wells with screening depth noted;*

*(iii) Depiction of the location of other samples used in the development of the model;*

*(iv) The upper and lower limits of the uppermost aquifer across the site;*

*(v) The upper and lower limits of the depth to groundwater measured from monitoring wells if the uppermost aquifer is confined; and*

*(vi) Both the location and geometry of any nearby points of groundwater discharge or recharge (e.g., surface waterbodies) with potential to influence groundwater depth and flow measured around the unit.*

## **2.1 Introduction**

This section provides information on site geology and hydrogeology, data used in site characterization, a summary of ALD-specific field and laboratory study, and a conceptual site model built using the Environmental Visualization System (EVS).

## **2.2 Site Geology**

The surficial topography of St. Clair County is characterized by a low-relief floodplain, stream terrace, and lakeshore deposits. The subsurface geology of the area is defined by glacial deposits, which range in thickness from 100- to 400-feet (ft) thick. These glacial sediments, including lacustrine, till, and sand and gravel outwash deposits, were deposited on the underlying bedrock. Throughout St. Clair County the underlying bedrock varies but is primarily fine-grained siliclastic rock, mostly shale with some sandstone [1].

The St. Clair River is the major surface water body in the county and runs along the eastern boundary of the county. Shallow regional groundwater flow would be expected to be to the east towards the St. Clair River. The DB is located approximately one mile west of the St. Clair River.

### **2.2.1 Diversion Basin Site-Specific Geology**

The geology of St. Clair County consists of approximately 100 to 400 ft of glacial deposits, primarily lacustrine deposits, till, and, to a lesser extent, sand and gravel outwash, overlying a variety of bedrock surfaces. The glacial material underlying the DB appears to be glaciolacustrine clays with local sand lenses. The uppermost aquifer unit appears to be associated with ice contact directly above the bedrock surface (Bedford Shale).

The DB is underlain by 115 to 130 ft of unconsolidated sediments, with the uppermost aquifer unit directly above the Bedford Shale. The uppermost aquifer unit is laterally consistent throughout the DB. During Geosyntec's ALD investigation in December 2020, cone penetration tests (CPT) and pore pressure dissipation (PPD) tests were performed to determine hydraulic conductivity of the underlying clay-rich deposits. The results of the PPD tests are summarized in Section 2.5.1.

The CPT data confirm that the underlying deposits are consistently low hydraulic conductivity units.

The uppermost aquifer unit within the DB is a confined, silty aquifer that directly overlies the Bedford Shale. It is approximately three to five feet in thickness and is encountered at approximately 115 to 130 ft below ground surface (bgs) directly below the bottom of the DB. To the northwest, the silty aquifer transitions into a sandy aquifer and increases in thickness; specifically, in the vicinity of the Bottom Ash Basins (BABs) located to the northwest. For the purposes of this report, the silty aquifer unit within the DB is considered the “uppermost aquifer unit” and is further discussed in Section 2.3.

### **2.3 Uppermost Aquifer Field Testing and Hydrogeology**

TRC calculated the hydraulic conductivities within the CCR monitoring wells set within the upper portion of the uppermost aquifer using single well hydraulic conductivity tests (e.g., slug tests) performed in 2016 by TRC [1]. Test results are provided in **Appendix A** and are included in the conceptual site model. The monitoring well logs and construction details are presented in **Appendix B**. As calculated by TRC, the hydraulic conductivity of the uppermost aquifer using wells at the DB (MW-16-05 and MW-16-07) is approximately 0.2 ft/day (7.0E-5 centimeters per second [cm/s]). This relatively low hydraulic conductivity indicates that the uppermost aquifer has low groundwater yield potential across the site. As discussed in the TRC Initial Application for Alternative Liner Demonstration, the potential horizontal groundwater flow is to the west-northwest. The uppermost aquifer is further discussed in Section 2.6.

### **2.4 Summary of Data Used for Site Characterization**

Data from three separate investigations were used to characterize the subsurface stratigraphy and soil characteristics for the site. Historical investigations included a 1973-1974 investigation performed by Bechtel and a 2016 investigation performed by TRC, which are included in the initial ALD Application [1]. Data from Geosyntec’s 2020 ALD Investigation were used to supplement the previous data sets. In total, these three investigations included 56 investigative locations that included 22 soil borings, 13 monitoring wells and 16 CPTs. **Figure 2-1** provides investigation locations.

Boring logs from the 1970s, 2016, and 2020 field investigations are provided in **Appendices C** through **E**, respectively. These investigations extend across the site and include the DB and BABs, which is approximately 400 ft northwest of DB. Considering the proximity of both CCR units, field investigation data are used for both the DB and BABs.

Field testing included pocket penetrometer tests on fine-grained soils, slug tests for the monitoring wells screened in the uppermost aquifer, and PPD tests at CPT locations. Lab testing included

grain size distributions, Atterberg limits, water content, dry and/or total unit weight, specific gravity, and hydraulic conductivity testing. Type of tests, standards and number of tests are summarized in **Table 2-1**. Laboratory test results are provided in **Appendices F** through **H** for the 1970s, 2016, and 2020 laboratory studies, respectively.

It is Geosyntec's opinion that the combined data used in building the site model are sufficient to capture the variability that may exist in soil conditions.

## **2.5 ALD-Specific Site Investigation Details**

The scope of work for the ALD-Specific Site Investigation (SI) was completed in December 2020 and included drilling and sampling and advancing a CPT probe through the native soils. The purpose of the fieldwork was to obtain nominally undisturbed samples for hydraulic conductivity testing and to supplement the existing data set to characterize the alternate liner materials in accordance with the CCR Rule. Investigations were conducted generally at 200-ft intervals but adjusted in the field as necessary to avoid underground utility lines, overhead power lines, and access issues, as needed. Investigations extended down to 100 ft bgs to an elevation of approximately 490 ft, which is lower than the groundwater elevation, and 20 ft below the nearest water body that is St. Clair River with a bottom elevation of approximately 525 ft.

The following sections provide a summary of the fieldwork completed during the SI.

### **2.5.1 Cone Penetration Tests**

Eight CPTs were completed around the DB in approximate 200 ft intervals along the east and south sides. Similarly, eight CPTs were completed around the BABs. Due to access issues to the area directly north and west of the DB, additional CPT locations were added to the south and southwest and CPT-08B/C was moved to the first accessible location west/northwest of the DB. The CPT locations are provided in **Figure 2-1**. CPTs were advanced from the ground surface to refusal or to approximately 100 ft bgs. PPD tests were conducted to estimate in-situ hydraulic conductivity at select depths; at a minimum, these tests were conducted near the sonic borings and at the elevation near where undisturbed samples were collected for laboratory hydraulic conductivity testing.

In total, 12 PPD tests were completed at CPTs advanced around the DB, and 16 PPD tests were completed at CPTs advanced around the BABs. Hydraulic conductivity values were estimated to range between  $7.97\text{E-}9$  cm/s and  $1.63\text{E-}6$  cm/s around the DB, and range between  $9.76\text{E-}9$  cm/s and  $2.81\text{E-}6$  cm/s around the BABs. Hydraulic conductivity values are similar between soils underlying the DB and BABs. Results are summarized in **Table 2-2**. These values are consistent with TRC's 2018 Natural Clay Liner Equivalency Evaluation Report [1].

CPT logs are provided in **Appendix I1**, and PPD tests are provided in **Appendix I2**.

## 2.5.2 Sonic Drilling

In December 2020, six soil borings were advanced at the site to evaluate the subsurface geology, collect undisturbed samples for hydraulic conductivity testing, and collect additional soil samples for characterization of native soils and the embankment. Soil samples were collected continuously in 2- to 10-ft sections from the ground surface to the termination of the soil boring. Geosyntec staff were present to log each boring and describe the soil samples in accordance with the Unified Soil Classification System (USCS).

Shelby tubes were collected from the DB embankment soils, and native soils at approximately 20 ft intervals from each of the sonic borings in accordance with ASTM D1587 [5]. The soil borings were advanced to depths of approximately 100 ft-bgs to within the uppermost aquifer and/or into the top of the underlying shale bedrock. Sonic drilling locations are provided in **Figure 2-1**. Boring logs are provided in **Appendix E**. Soil stratigraphy is discussed in Section 2.6.

## 2.5.3 Laboratory Testing

A suite of index testing and hydraulic conductivity testing was conducted on select soil samples. Fourteen soil samples were collected from six borings from depths between 5 ft-bgs and 90 ft-bgs for hydraulic conductivity testing to capture soft to very stiff soils. Details of hydraulic conductivity testing are provided in Section 3.

Index testing included:

- 24 Moisture Content tests (ASTM D2216)
- 4 Specific Gravity tests (ASTM D854)
- 22 Grain Size Mechanical Sieve tests (ASTM D6913)
- 21 Atterberg Limits tests (ASTM D4318)

Note that these tests are included in **Table 2-1**. Test results are provided in **Appendix H**.

## 2.6 Conceptual Site Model

An EVS model was developed for the site based on data collected during the field investigations from the 1970s, 2016, and 2020. The EVS model centralized all the data to develop a comprehensive conceptual site model. Based on the EVS model, the overall conceptual site model of the DB lithology is relatively consistent with low hydraulic conductivity clay-rich deposits with non-interconnected sand seams at greater depths. Within the DB footprint, the uppermost aquifer

unit sits directly above the bedrock and is relatively consistent at approximately 10 ft thick across the DB.

Specific to the DB, cross-sections (**Figures 2-2 through 2-5**) were created from the EVS model and analyzed to determine the various changes in lithology within the clay confining unit directly underlying the DB and the characteristics of the uppermost aquifer unit which sits directly on the bedrock. Upon review of the transects, the lithology beneath the DB consists of (from the ground surface downward) (1) clay, (2) clay with sand, (3) uppermost aquifer unit, and (4) shale bedrock. These units are consistent with historical reports and TRC's November 2020, Initial Application for Alternate Liner Demonstration [1]. There were some discrepancies, in that the second clay unit was described as silty instead of sandy. Based on CPT and geotechnical index testing during Geosyntec's 2020 ALD investigation, the lower clay was re-interpreted as "clay with sand" mainly due to the increased sand seams that were encountered. The clay within the "clay with sand" unit is relatively constant stiff gray clay. Therefore, the lithology directly underlying the DB consists of the following:

- (1) Clay – 35 to 40 ft thick directly beneath the DB. This unit consists of mainly soft to medium stiff clay and minimal sand seams. None of the sand seams are interconnected or considered an aquifer unit.
- (2) Clay with sand – This unit was encountered at approximately 35 to 40 ft bgs with a thickness of approximately 80 to 90 ft. This unit consists of stiffer gray clay with increasing sand seams. Although there are more frequent sand seams, most are less than 2 ft in thickness and have hydraulic conductivity values greater than  $1.0E-7$  cm/s except for one location which is discussed in more detail below. The data supports that none of the sand seams are interconnected or considered an aquifer unit. Consequently, because the sands are isolated, the unit behaves like a low hydraulic conductivity clay unit.
- (3) Uppermost Aquifer Unit – This unit was encountered at approximately 115 to 130 ft bgs. The thickness of the unit is relatively consistent at 3- to 5-ft thick and directly sits atop the bedrock. This silty unit is saturated and considered the uppermost aquifer unit within the DB. There is a transition from the silty aquifer beneath the DB to a thicker sandy aquifer beneath the BABs located to the north/northwest of the DB. Both are considered the "uppermost aquifer unit" on the cross sections and within the EVS model.
- (4) Shale bedrock – This unit was encountered at approximately 100-130 ft bgs.

During Geosyntec's 2020 investigation, CPT tests were conducted and PPD tests were completed at CPT-08B, CPT-08C, CPT-11, CPT-12 and CPT-13B to estimate the hydraulic conductivity of the lithology. In addition, laboratory testing was conducted on individual grab samples from the three sonic borings around DB for long-term breakthrough potential and is further discussed in

Section 3. Based on the review of the PPD test data, values ranged between  $7.97\text{E-}9$  cm/s and  $1.63\text{E-}6$  cm/s around the DB. The CPT-derived highest hydraulic conductivity value of  $1.63\text{E-}6$  cm/s was calculated at CPT-13B from a sand seam at 490 ft above mean sea level (AMSL) (approximately 100 ft bgs) within the (2) clay with sand unit. PPD tests at CPT-13 and CPT-12 located next to CPT-13B indicated hydraulic conductivities less than  $1.0\text{E-}7$  cm/s. Therefore, the (1) clay and (2) clay with sand lithologies beneath the DB have adequate hydraulic conductivity values to be considered a low hydraulic conductivity unit and is consistent with TRC's 2018 Natural Clay Liner Equivalency Evaluation Report [1].

Below the clay with sand is the uppermost aquifer unit that mainly consists of silt. This unit directly overlies the Bedford shale. Beyond the DB, the EVS model predicts this unit extending to the BABs with increasing sands. The hydraulic head in the (3) uppermost aquifer unit associated with the DB is approximately 575 ft AMSL [1] with a gradient to the west-northwest.

The bottom of the DB is at an elevation of approximately 576 ft and the bottom of the clay underlying the DB is at an elevation of approximately 450 ft AMSL, thus more than 120 ft of low hydraulic conductivity clay-rich deposits ((1) clay and (2) clay with sand) separate the bottom of the DB from the underlying (3) uppermost aquifer unit.

### 3. POTENTIAL FOR INFILTRATION

The CCR Rule requires:

*§257.71(d)(ii)(B) Potential for infiltration. A characterization of the potential for infiltration through any soil-based liner components and/or naturally occurring soil that control release and transport of leachate. All samples collected in the field for measurement of saturated hydraulic conductivity must be sent to a certified laboratory for analysis under controlled conditions and analyzed using recognized and generally accepted methodology. Facilities must document how the selected method is designed to simulate on-site conditions. The owner or operator must also provide documentation of the following as part of this line of evidence:*

- (1) The location, number, depth, and spacing of samples relied upon is supported by the data collected in paragraph (d)(1)(ii)(A) of this section and is sufficient to capture the variability of saturated hydraulic conductivity for the soil-based liner components and/or naturally occurring soil;*
- (2) The liquid used to pre-hydrate the samples and measure long-term hydraulic conductivity reflects the pH and major ion composition of the CCR surface impoundment porewater;*
- (3) That samples intended to represent the hydraulic conductivity of naturally occurring soils (i.e., not mechanically compacted) are handled in a manner that will ensure the macrostructure of the soil is not disturbed during collection, transport, or analysis; and*
- (4) Any test for hydraulic conductivity relied upon includes, in addition to other relevant termination criteria specified by the method, criteria that equilibrium has been achieved between the inflow and outflow, within acceptable tolerance limits, for both electrical conductivity and pH.*

#### 3.1 Site-Specific Soil and Porewater Details

##### 3.1.1 Soil Samples for Hydraulic Conductivity Testing

Fourteen site-specific soil samples were collected for hydraulic conductivity testing. Considering the extent of existing field investigation data, including CPTs with PPDs and earlier borings, Geosyntec believes that the collected samples are sufficient to capture the variability of hydraulic conductivity in the natural soils present at the DB.

### 3.1.2 Site-Specific Porewater Testing and Results

Site-specific CCR porewater samples were collected from both the DB and the BABs for geochemical analyses to assess the representative composition of an “aggressive” solution for use in the hydraulic conductivity compatibility testing. Due to the high turbidity of basin waters, samples were filtered through a 0.45-micron filter to evaluate dissolved concentrations. Site-specific porewater samples were tested for CCR Rule Appendix III and Appendix IV parameters as well as additional major cations (sodium, magnesium, potassium), anions (total alkalinity), iron, and manganese.

All porewater samples were found to be slightly basic, with pH concentrations ranging from 7.87 to 9.01 SU. Total dissolved solids (TDS) concentrations of all three samples are similar, ranging from 200 to 300 milligrams per liter (mg/L). All three samples have TDS concentrations < 1000 mg/L, which is defined by the United States Geological Survey (USGS) as “freshwater”. The DB and BAB samples have similar major ion compositions, as illustrated on the Piper diagram in **Figure 3-1**. The anion composition is very similar for all three samples and consists of predominantly sulfate with some alkalinity and very little chloride. The cation composition is predominantly calcium and monovalent cations (potassium/sodium), with a smaller proportion of magnesium. The DB sample has a slightly higher relative percentage of calcium and lower monovalent cations compared to the BAB samples.

The analytical results are provided in **Appendix J** and tabulated in **Table 3-1**. Results were used to calculate total ionic strength for each sample. Total ionic strength is a measure of the combined ion concentrations in a solution and can represent the salinity of a sample. Total ionic strength was calculated for each sample using geochemical modeling software Geochemist’s Workbench (GWB) v12.0.4. The GWB thermodynamic dataset ‘thermo.com.V8.R6\_.tdat’ was used for the calculations in order to incorporate all tested parameters. Analytical results for each parameter were input into GWB in units of mg/L and the ionic strength of each sample was calculated in units of molality (m).

Both BAB samples contained similar ionic strength values (0.0088 and 0.0080 m) compared to the slightly higher ionic strength of the DB sample (0.0106 m). Thus, the DB sample is considered to be the more aggressive solution and was used for compatibility testing as described in Section 3.2.

### 3.2 Hydraulic Conductivity Testing Procedure

Eight soil samples were tested for hydraulic conductivity,  $k$ , using deionized water in accordance with ASTM D5084 [6] to establish a baseline hydraulic conductivity. The other six samples were selected for compatibility testing in accordance with ASTM D7100 [7] using site-specific porewater. The use of ASTM D7100 is discussed in the preamble of the CCR Rule and deemed appropriate by USEPA.

ASTM D7100 termination criteria require the following conditions:

- The ratio of outflow to inflow is between 0.75 and 1.25.
- The hydraulic conductivity is steady, defined as four or more consecutive hydraulic conductivity measurements falling within  $\pm 25\%$  of the mean value for hydraulic conductivity if the mean hydraulic conductivity is greater than or equal to  $1.0\text{E-}8$  cm/s or within  $\pm 50\%$  if the mean hydraulic conductivity is less than  $1.0\text{E-}8$  cm/s, and a plot or tabulation of the hydraulic conductivity versus time shows no significant upward or downward trend;
- At least 2 pore volumes (PV) of flow has passed through the sample; and
- pH and electrical conductivity of effluent are within 10% of that for the influent with no significant increasing or decreasing trends.

### 3.3 Hydraulic Conductivity Test Results and Assessment

The final measured hydraulic conductivities based on ASTM D5084 for the samples range from  $2.7\text{E-}9$  to  $2.2\text{E-}8$  cm/s. **Table 3-2** presents a summary of the measured hydraulic conductivities for the samples and more details are provided in **Appendix H**.

Results for the hydraulic conductivity compatibility tests are provided in **Appendix K** with measurements through December 23, 2022 and summarized in **Table 3-3**. The table provides sample ID, the start date for testing, amount of PV passed through the sample, and hydraulic conductivity measurements.

A set of figures are included to present:

- PV passed with time;
- hydraulic conductivity with time;
- hydraulic conductivity versus PV passed;
- pH of inflow and outflow with time; and
- electrical conductivity (EC) of inflow and outflow with time.

These plots are provided in **Figures 3-2** through **3-31**.

The final measured hydraulic conductivities of samples range between  $4.4\text{E-}9$  and  $2.1\text{E-}8$  cm/s. The amount of PV that passed through the samples range from 2.8 to 10.5. All samples have passed

more than 2 PV to satisfy the termination criterion. The hydraulic conductivities generally remained steady with time and PV passed.

pH measurements are provided in **Table 3-4**. The average pH of inflow ranges from 8.2 to 8.4, and the average pH of outflow ranges from 8.2 to 8.4. The average pH of outflow are within 10 percent of the average pH of inflow.

EC measurements are provided in **Table 3-5**. The average EC of inflow ranges from 1,030 to 1,098, and the average EC of outflow ranges from 874 to 1,381. The EC measurements of outflow are within 10% of the EC measurements of inflow for sample B1-ST-1. The EC measurements of outflow were within 10% of the EC measurements of inflow for the other samples for at least one measurement; however, the outflow and inflow EC measurements are not within 10% as of December 2022.

**Table 3-6** summarizes if the samples have reached the termination criteria for PV, hydraulic conductivity, pH, and EC in December 2022. As summarized in the table, all samples have reached the termination criteria for PV passed, hydraulic conductivity, and pH. One sample (B1-ST-1) has reached the termination criterion for EC, though the other samples satisfied this criterion at some point during testing. Overall, the average hydraulic conductivity measurements for the samples ( $6.9\text{E-}9$  to  $2.6\text{E-}8$  cm/s) have remained steady or slightly decreased from the average measurements ( $8.2\text{E-}9$  to  $2.2\text{E-}8$  cm/s) presented in the PALD [4]. Only the average hydraulic conductivity measured for sample B4-ST-3 ( $1.8\text{E-}8$  to  $2.6\text{E-}8$  cm/s) increased from the PALD [4].

The results do not present inflow versus outflow data. The project team decided to keep the inflow constant to provide a more stable hydraulic gradient across the sample, more accurate estimation of hydraulic conductivity, , faster testing, and more control in the testing procedure. It is Geosyntec's opinion that the inflow/outflow criterion was satisfied during the two years of testing because of the consistently low hydraulic conductivity results and constant hydraulic conductivity measurements (not significantly increasing or decreasing)..

#### 4. FATE AND TRANSPORT MODEL ANALYSES

The CCR Rule requires:

*§257.71(d)(ii) (C) Mathematical model to estimate the potential for releases. Owners or operators must incorporate the data collected for paragraphs (d)(1)(ii)(A) and (d)(1)(ii)(B) of this section into a mathematical model to calculate the potential groundwater concentrations that may result in downgradient wells as a result of the impoundment. Facilities must also, where available, incorporate the national-scale data on constituent concentrations and behavior provided by the existing risk record. Application of the model must account for the full range of site current and potential future conditions at and around the site to ensure that high-end groundwater concentrations have been effectively characterized. All the data and assumptions incorporated into the model must be documented and justified.*

*(1) The models relied upon in this paragraph (d)(1)(ii)(C) must be well- established and validated, with documentation that can be made available for public review.*

*(2) The owner or operator must use the models to demonstrate that, for each constituent in appendix IV of this part, there is no reasonable probability that the peak groundwater concentration that may result from releases to groundwater from the CCR surface impoundment throughout its active life will exceed the groundwater protection standard at the waste boundary.*

*(3) The demonstration must include the peak groundwater concentrations modeled for all constituents in appendix IV of this part attributed both to the impoundment in isolation and in addition to background.*

##### 4.1 Introduction

A fate and transport model analysis was performed to evaluate whether the peak groundwater concentrations that may result from releases to the groundwater from the DB exceeds the GWPS at the waste boundary throughout its active life.

The model considers flow of CCR porewater Constituents of Concern (COCs) migrating through the bottom of the DB down to the uppermost aquifer. The model does not consider additional migration of COCs horizontally to the waste boundary. If considered, the horizontal groundwater flux would reduce the concentrations of the COCs, thus, the model presents a conservative assessment.

According to §257.71(2)(ii)(C)(3), the owner must submit “...a final demonstration that updates only the finalized hydraulic conductivity data to confirm that the model results in the preliminary demonstration are accurate.” The hydraulic conductivity used in the calculation of the Darcy

velocity for the baseline fate and transport model corresponds to the geometric mean of all available data. For the PALD [4], a hydraulic conductivity of  $2.15\text{E-}8$  cm/s was used for the baseline model. The recalculated geometric mean hydraulic conductivity based on the updated laboratory test results presented in Section 3.3 is approximately  $2.14\text{E-}8$  cm/s, or a decrease of less than 1%. Furthermore, a sensitivity analysis was performed as part of the fate and transport analyses in the PALD [4] that captured this change in hydraulic conductivity data within the range of hydraulic conductivities evaluated. Therefore, the model results for the fate and transport analysis presented in the PALD [4] are considered accurate and not updated for this ALD. The following sections summarize the fate and transport analyses from the PALD for convenience.

As discussed in Section 4.6.1, the results of the model predict COC concentrations that are very low such that there is no reasonable probability that water from the DB will cause releases to the groundwater that will exceed the GWPS at the waste boundary over the projected active life of the DB.

#### **4.2 Groundwater Protection Standards**

Groundwater samples from TRC's 2016 and 2017 sampling events were tested for Appendix IV COCs and represent eight rounds of background groundwater data. The data were used to calculate site-specific background levels (background) for Appendix IV COCs. **Appendix L** provides the memorandum describing the statistical calculations.

To develop GWPS for the ALD, the federal Maximum Contaminant Level (MCL), Regional Screening Levels, and site-specific background were evaluated and the highest value was selected as the GWPS in accordance with the CCR Rule. Where MCL are not available Regional Screening Levels were used. GWPS are provided in **Table 4-1**.

#### **4.3 Consideration of Background Groundwater Concentrations**

The site-specific background has been considered and is a factor when determining if GWPS have been exceeded. At the DB, naturally occurring background concentrations are generally much lower than the GWPS. The predicted groundwater concentrations and the peak background concentrations are further discussed in Section 4.6.1.

#### **4.4 CCR Porewater Quality Results**

CCR porewater quality samples from the DB and the BABs were collected in December of 2020 and January of 2021. Samples were analyzed for Appendix III and IV parameters by ALS Environmental in Holland, MI. Analytical results were compared for each parameter and the highest CCR porewater concentration was used as the established concentration of the constituent ( $C_o$ ) when calculating the predicted groundwater concentrations (PGC<sub>i</sub>), as discussed further below. The CCR porewater quality data is summarized in **Table 4-2**.

In addition to the site-specific CCR porewater concentrations, 90<sup>th</sup> percentile concentrations from the 2014 EPA study [8] were considered in the analysis. This data is summarized in **Table 4-2**.

## 4.5 Fate and Transport Model

### 4.5.1 Analysis Model

A one-dimensional fate and transport model was designed to further understand the potential for contaminant transport from the DB to the uppermost aquifer. The model was developed with a contaminant transport process through the clay and clay with sand layers under the DB. Contaminant transport processes are discussed in Section 4.5.2.

The modeling program POLLUTE [9] was selected for the one-dimensional fate and transport evaluation. POLLUTE uses the input parameters to perform calculations for individual transport processes, and then uses the semi-analytical solution for the various transportation process (see Section 4.5.2) to yield predicted concentrations at the various specified times and distances.

Model setup and inputs are discussed in detail in the following sections and are summarized by layer in **Figure 4-1**.

### 4.5.2 Proposed Mathematical and Associated Computer Model

#### 4.5.2.1 *Mathematical Model*

The potential transport mechanisms that may occur at the DB for the various modeled layers include advection, mechanical dispersion and diffusion. For porous media, these transport mechanisms can be represented by the following one-dimensional flow equation [10]:

$$\textbf{Equation No. 1:} \quad n \frac{\delta c}{\delta t} = nD \frac{\delta^2 c}{\delta z^2} - V_{\alpha} \frac{\delta c}{\delta z} - \rho K_d \frac{\delta c}{\delta t} - n\lambda c$$

Where:

c = concentration at any point

D = coefficient of hydrodynamic dispersion in the vertical direction

n = porosity of the geologic layer

K<sub>d</sub> = distribution coefficient

V<sub>α</sub> = Darcy velocity in the vertical direction

$\rho$  = dry density of soil

$\lambda$  = decay constant of the contaminant species

t = time

POLLUTE utilizes the transport phenomena as governed by Equation No. 1.

#### 4.5.2.2 *Predicted Groundwater Concentrations*

This model uses an initial concentration value of one (1), which represents a unit concentration of any constituent in the CCR porewater. The results from the model can thus be used as a prediction factor for estimating the future concentration of any constituent of concern in groundwater. Multiplying the output prediction factor by the initial CCR porewater concentration provides the predicted groundwater concentration at the end of the model run. The following equation (Equation No. 2) illustrates this concept:

$$\text{Equation No. 2: } \text{PGC}_t = \text{PF}_t * C_o$$

Where:

$\text{PGC}_t$  = predicted groundwater concentration after t years.

$\text{PF}_t$  = prediction factored after t years, which is the output of the model.

$C_o$  = established CCR porewater concentration of the constituent of concern.

### 4.5.3 Fate and Transport Model Inputs

#### 4.5.3.1 *Initial CCR Porewater or Source Concentration*

The initial CCR porewater concentration input value used was unity (1). This value is unitless because it represents unit CCR porewater concentration of any given constituent. Therefore, the model results represent a fraction of the initial CCR porewater concentration for any constituent.

#### 4.5.3.2 *Number of Layers and Layer Thickness*

Two layers were modeled at the site: the clay layer and the clay with sand layer. At the DB, the clay layer has an average thickness of 36 ft; the clay with sand layer has an average thickness of 84 ft. The average thickness of each layer was derived from an isopach map generated by subtracting the surface representing the bottom of the layer from the surface representing the top of the layer and averaging the difference over the footprint of the DB. Model documentation for the average thickness of each layer can be found in **Appendix M**.

POLLUTE also allows layers to be subdivided into sublayers, which allows the predicted concentration distribution within a layer to be calculated. The clay layer was divided into 20 sublayers at the DB. The clay with sand layer was divided into 50 sublayers at the DB.

#### 4.5.3.3 *Modeling Period*

The model was run for the operating period of 55 years. This modeling period captures the amount of time elapsed from the 1980s, when operations started at the DB, to 2034, which is the end of the projected active life of the DB.

#### 4.5.3.4 *Talbot Parameters*

POLLUTE uses a Laplace transform to find the solution to the advection-dispersion equation. The numerical inversion of the Laplace transform depends on the Talbot parameters. The model provides default values for the parameters, or they can be selected by the user. The default Talbot parameters were used in this demonstration [11].

#### 4.5.3.5 *Boundary Conditions*

POLLUTE allows the user to select between multiple upper and lower boundary conditions. The top boundary condition typically represents the bottom of the CCR unit as a potential source. The top boundary can be specified as either zero flux, constant concentration, or finite mass. A constant concentration was assumed as it provides conservative model results because it assumes that the leachate quality will remain constant at the maximum measured values over time.

The lower boundary can be specified as either zero flux, constant concentration, fixed outflow, or infinite thickness. For this model, an infinite thickness lower boundary was used. Therefore, the model output is a prediction factor of contaminant concentration in groundwater at the interface between the clay with sand layer and the underlying uppermost aquifer.

#### 4.5.3.6 *Darcy Vertical Velocity*

POLLUTE requires a Darcy velocity to be input for the model as a whole. The Darcy velocity was calculated for the DB using a vertical gradient and the vertical hydraulic conductivity of the clay with sand layer. For the DB, the vertical gradient was calculated using hydrogeologic data from the uppermost aquifer and the elevation of the typical operation water level within the DB. These parameters were chosen to produce a conservative value for the Darcy velocity. A Darcy velocity value of  $2.03\text{E-}4$  m/year was calculated for the DB as provided in **Appendix M**. The hydraulic conductivity value used for the calculation of Darcy velocity is the average (geometric mean) of historical and current lab testing for the vertical hydraulic conductivity data.

#### 4.5.3.7 *Hydrodynamic Dispersion Coefficient*

The vertical coefficient of hydrodynamic dispersion is a required input for each layer within the POLLUTE model. The hydrodynamic dispersion coefficient is calculated using Equation No. 3:

$$\text{Equation No. 3: } D = D^* + av$$

Where:

D = the hydrodynamic dispersion coefficient (m<sup>2</sup>/year);

D\* = the effective diffusion coefficient (m<sup>2</sup>/year).

a = the dispersivity (m);

v = the groundwater seepage velocity (m/year).

For this demonstration, a coefficient of hydrodynamic dispersion value (D) of 0.19 m<sup>2</sup>/year was input into the model. This value was based on the effective diffusion coefficient (D\*) for chloride 0.19 m<sup>2</sup>/year, as calculated by Rowe et al. [12]. The coefficient of chloride was chosen as it is considered to have a high capacity for diffusion compared to other constituents of interest. Therefore, it is a conservative constituent to model among the COCs.

The second part of Equation 3, the product of dispersivity and groundwater seepage velocity, is related to dispersion. Rowe et al. [12] discusses when the seepage velocity (2.03E-4 m/year) is low (i.e., clay soils), diffusion will control the hydrodynamic dispersion (D) and dispersion is negligible.

#### 4.5.3.8 *Effective Porosity and Density Input*

The average porosity of each model layer was estimated using laboratory data as discussed in Section 2. The model shows good agreement between porosity values and geologic layers, with the overlying clay unit having lower porosities than the underlying clay with sand unit. An average of 51 percent porosity was used for the clay layer, while an average of 63 percent porosity was used for the clay with sand layer.

Based on empirical data provided by Sara [13], the laboratory porosity data was converted to effective porosities. Effective porosity values of 0.41 and 0.51 were used for the clay and clay with sand layers, respectively.

Density values from laboratory testing were also used to determine a suitable model input. The average density of 1,500 kg/m<sup>3</sup> (94.2 pcf) was estimated from the available data. This value was used in the POLLUTE model.

#### 4.5.3.9 *Adsorption Coefficient and Degradation*

Adsorption and degradation of constituents can play a significant role in the impedance of contaminant migration in the subsurface. Within POLLUTE, the adsorption coefficient simulates the impedance of constituents or sorption of contaminants in the modeled layers, while degradation simulates the breakdown of contaminants over time. In this model, adsorption and degradation are assumed to be zero, which provides a more conservative model result.

### 4.6 Fate and Transport Analysis Results and Evaluation

#### 4.6.1 Fate and Transport Baseline Model Results

The modeling was performed to evaluate predicted groundwater quality based on the hydrogeology of the site. At the DB, the baseline model calculated a  $PF_t$  of 6.35E-40. With both the  $C_o$  and  $PF_t$  established, the  $PGC_t$  (i.e., predicted concentration) was calculated and compared to the established GWPS for the DB. As provided in **Table 4-3**, the predicted groundwater quality results are below the GWPS levels. In addition, the predicted concentrations were added to the highest concentrations that were measured in the 2016-2017 groundwater sampling events and compared to the GWPS. The combined results from predicted concentrations and the highest measured concentrations are below the GWPS (see **Table 4-3**). Therefore, no impacts to groundwater above GWPS are predicted over the duration of the active life of the DB.

The driving mechanism for the transport is chemical diffusion, because the advective flow would take more than a thousand years for a water molecule to travel from the bottom of the DB to the uppermost aquifer. **Appendix M** provides calculations for the time of travel.

The baseline model outputs for the DB are included in **Appendix N**.

#### 4.6.2 Sensitivity Analysis

Many of the model inputs are specific to the site. Given the potential for sampling bias, uncertainty, and natural variation, a sensitivity analysis was conducted to evaluate the impact on the variation of the model inputs. The analysis focused on changes to the model output, or  $PF_t$ , given a variation to a single model input as discussed in the following sections. A summary of the sensitivity analyses model input values is provided in **Table 4-4**.

The resulting  $PF_t$  from each sensitivity analysis was compared to a threshold prediction value,  $PF_{\text{threshold}}$ . The  $PF_{\text{threshold}}$  value represents the  $PF_t$  at which impacts to groundwater are predicted for Appendix IV COCs at the top of the uppermost aquifer under the DB.  $PF_{\text{threshold}}$  is calculated using Equation 4:

$$\text{Equation No. 4: } PF_{\text{threshold}} = \min \left\{ \frac{GWPS_1}{C_1}, \frac{GWPS_2}{C_2}, \dots, \frac{GWPS_i}{C_i}, \dots, \frac{GWPS_n}{C_n} \right\}$$

Where:

$PF_{\text{threshold}}$  = threshold prediction factor

$GWPS_i$  = groundwater protection standard for constituent ‘i’

$C_i$  = maximum porewater concentration of the COC ‘i’

#### 4.6.2.1 *Darcy Velocity*

A sensitivity analysis was completed to evaluate the impact of Darcy velocity. A Darcy velocity of 4.07E-4 m/year was selected as the value to use for this analysis. This value is double the baseline value calculated during this demonstration and thus serves as a suitable value for input to the sensitivity analysis.

#### 4.6.2.2 *Coefficient of Hydrodynamic Dispersion*

Model sensitivity to the coefficient of hydrodynamic dispersion was evaluated by increasing and decreasing the input value by 25%. The initial input value was derived from laboratory testing [12], and thus a 25% increase and decrease is considered a satisfactory variation for the purposes of a sensitivity analysis.

#### 4.6.2.3 *Porosity and Effective Porosity*

Model sensitivity to the porosity and effective porosity was evaluated by increasing and decreasing the input value by the minimum and maximum range of values calculated from the laboratory results.

#### 4.6.2.4 *Layer Thickness*

The isopach maps (**Appendix M**) were used to calculate the maximum and minimum thickness for the clay and clay with sand layers. Using those values as inputs, four additional models were run for the DB to evaluate model sensitivities to layer thickness. In each model only one variable was changed.

#### 4.6.2.5 *Modeling Period*

The modeling period used was 55 years (the “baseline”). To further evaluate the impact of modeling runtime on the resultant  $PF_t$ , one model was run with a modeling period of 85 years, to capture the post-closure care period.

#### 4.6.2.6 *Sensitivity Results*

Additional fate and transport model runs were completed to evaluate model sensitivities to changing model inputs. As shown in **Table 4-5**, using more conservative model input parameters resulted in  $PF_t$  values ranging from 5.19E-47 to 1.14E-32. This demonstrates that the DB will not impact groundwater quality assuming conditions more conservative than the baseline scenario. The sensitivity modeling results are presented in **Table 4-5** whereas the model outputs are included in **Appendix N**.

#### 4.6.3 Reliability of Computer Model

The computer-based fate and transport model used for this analysis is based on rigorous and proven analytical solutions to the advection-dispersion equation for layered deposits. These equations were derived with the intent of modeling the physical and chemical transport of contaminants from waste impoundments. Widespread use, comprehensive documentation, and abundant publications ([10], [14], [11], [15], [16]) demonstrate the versatility of this modeling approach for assessing groundwater impacts. The outputs obtained from models conducted in POLLUTE can be compared to those obtained using other approaches to solving the advection-dispersion equation.

#### 4.6.4 Degree of Conservativeness in Model Results

Input parameters for the baseline models were based on site-specific data whenever possible. When not possible, input values were derived from an understanding of the site and relevant peer-reviewed literature. If a high degree of uncertainty was present, conservative input values were selected. A summary of the various conservative assumptions are listed below:

- The maximum measured CCR porewater concentration for each constituent was used for the fate and transport model prediction table;
- Constant CCR porewater concentration or a constant mass was used for the entire modeling period. A specific mass could have been assumed for modeling purposes which would have resulted in decreased CCR porewater concentrations over time, but to be conservative the model considered constant CCR porewater concentration over time;
- Adsorption can significantly reduce the concentrations of metal constituents as they move through soils, especially clays which would retard or slow down the migration. To be conservative, the model assumes no adsorption would occur over time;
- Degradation of concentrations (input values) through either the biologic or chemical process was assumed not to occur during the modeling period. By assuming no degradation, the model overestimates the predicted groundwater quality over time; and

- The CCR Rule requires compliance at the waste boundary. The analysis only considers vertical flow from the bottom of the DB to the top of the uppermost aquifer; the analysis does not consider a horizontal flow towards the waste boundary, which would further lower the predicted concentration levels for COCs.

## 5. SUMMARY

This ALD has been prepared to assess if the DB meets the ALD requirements per the CCR Rule. The data included comprehensive field and laboratory investigation data collected from the 1970s to 2020. The 2020 field and laboratory investigation studies were conducted specifically to fill data gaps and to address the CCR Rule requirements. The data were incorporated into an EVS model to create a comprehensive conceptual site model to understand the lithology beneath the DB and as a basis for the fate and transport analysis. The EVS model was relatively consistent with historical representations of the geology associated with the DB.

Site-specific water was collected from the DB and BABs and tested to assess which one of the CCR units had the more aggressive water. Water from DB was deemed to be more aggressive and used for compatibility testing to estimate the impacts on hydraulic conductivity of site-specific soil samples. The results of the testing program are presented in this ALD. .

A comprehensive subsurface stratigraphy model was created using the available data set incorporated into the conceptual site model. Fate and transport analyses were conducted to assess whether there is a reasonable probability that water from the DB may result in a release to the groundwater during its active life that would exceed the GWPS at the waste boundary. The baseline fate and transport analysis was conducted using the available site-specific data and an operating period of 55 years, which captures the period from the 1980s, when operations started at the DB, to 2034, which is the end of the projected active life of the DB.

The analysis considered different contaminant transport mechanisms including, advection, dispersion, and diffusion. The analysis indicates that advective flow would take more than a thousand years for a water molecule to travel from the bottom of the DB to the uppermost aquifer. Therefore, the analysis results indicate that, due to the low hydraulic conductivity of the in-situ soils, chemical diffusion is the dominant transport mechanism compared to advection or seepage velocity. Consequently, the hydraulic conductivity testing described in Section 3 is sufficient to characterize hydraulic conductivity and demonstrate the performance of the alternate liner system as it relates to advection or seepage flow.

A sensitivity analysis was performed as part of additional fate and transport analyses to account for sampling bias, uncertainty, and natural variation in site-specific inputs. Predicted groundwater concentrations for both the baseline and sensitivity analyses are below GWPS. The sensitivity analyses results show that there is no reasonable probability that water from the DB will result in a release to the groundwater that would exceed the GWPS at the waste boundary over the projected active life of the DB.

**6. CERTIFICATION**

**CCR Unit:** DTE Electric Company; Belle River Power Plant, Diversion Basin (DB)

I, Clinton P. Carlson, being a Registered Professional Engineer in good standing in the State of Michigan, do hereby certify in accordance with the CCR Rule, to the best of my knowledge, information, and belief, that the information contained in this plan has been prepared in accordance with the accepted practice of engineering and that the DB meets the requirements of the Alternative Liner Demonstration per the CCR Rule.

Dv = Vertical Darcy Velocity

CoHD = Coefficient of Hydrodynamic Dispersion

**Table 4-5 – Sensitivity Analysis Model Results**

<b>Diversion Basin Sensitivity Analysis</b>			
<b>Model Name</b>	<b>Description</b>	<b>Prediction Factor</b>	<b>Pass?*</b>
DB_Baseline	Baseline model for the Bottom Ash Basins.	6.35E-40	YES
DB_ExtendedRun	Model runtime was extended from 55 years to 85 years.	1.14E-32	YES
DB_Darcy	Darcy velocity was doubled.	9.60E-40	YES
DB_CoHD_High	Coefficient of Hydrodynamic Dispersion was increased by 25%.	8.53E-36	YES
DB_CoHD_Low	Coefficient of Hydrodynamic Dispersion was decreased by 25%.	5.19E-47	YES
DB_ClayPoro_High	Used the highest effective porosity in clay interval; derived from laboratory data in project database.	6.98E-40	YES
DB_ClayPoro_Low	Used the lowest effective porosity in clay interval; derived from laboratory data in project database.	6.08E-40	YES
DB_SandPoro_High	Used the highest effective porosity in clay with sand interval; derived from laboratory data in project database.	6.06E-40	YES
DB_SandPoro_Low	Used the lowest effective porosity in clay with sand interval; derived from laboratory data in project database.	8.29E-40	YES
DB_ClayThick	Used thickest clay interval seen in boring/well; derived from project database.	4.18E-41	YES
DB_ClayThin	Used thinnest clay interval seen in boring/well; derived from project database.	1.96E-39	YES
DB_SandThick	Used thickest clay with sand interval seen in boring/well; derived from project database.	2.76E-41	YES
DB_SandThin	Used thinnest clay sand interval seen in boring/well; derived from project database.	8.74E-39	YES
* Indicates value less than $PF_{\text{threshold}}$ as discussed in Section 4.6.2.

		Rising Head	7.21E-05	0.204
		<b>Average</b>	<b>9.79E-05</b>	<b>0.277</b>
<b>Minimum</b>			<b>3.19E-05</b>	<b>9.05E-02</b>
<b>Maximum</b>			<b>3.15E-04</b>	<b>8.92E-01</b>
<b>Geometric Mean</b>			<b>8.77E-05</b>	<b>0.249</b>

**Conversion:**

$$\frac{1 \text{ cm}}{1 \text{ sec}} \times \frac{86,400 \text{ sec}}{1 \text{ day}} \times \frac{1 \text{ ft}}{30.48 \text{ cm}} = 2.83\text{E}+03 \frac{\text{ft}}{\text{day}}$$

**Notes:**

Slug test results calculated using the Bower-Rice (1976) Solution.

MW-16-01 RISING HEAD SLUG TEST

Data Set: P:\...\MW-16-01\_OUT.aqt  
 Date: 05/22/17

Time: 13:40:08

PROJECT INFORMATION

Company: TRC Environmental Corporation  
 Client: DTE EC BRPP CCR  
 Project: 231828.0003.0000  
 Location: China Township, MI  
 Test Well: MW-16-01  
 Test Date: 4/13/16

AQUIFER DATA

Saturated Thickness: 52. ft

Anisotropy Ratio (Kz/Kr): 1.

WELL DATA (MW-16-01)

Initial Displacement: 1.138 ft  
 Total Well Penetration Depth: 84.07 ft  
 Casing Radius: 0.08333 ft

Static Water Column Height: 84.07 ft  
 Screen Length: 5. ft  
 Well Radius: 0.08333 ft

SOLUTION

Aquifer Model: Confined  
 K = 0.0002716 cm/sec

Solution Method: Bouwer-Rice  
 y0 = 0.7541 ft

MW-16-04 FALLING HEAD SLUG TEST

Data Set: P:\...\MW-16-04\_IN.aqt  
 Date: 05/22/17

Time: 13:41:00

PROJECT INFORMATION

Company: TRC Environmental Corporation  
 Client: DTE EC BRPP CCR  
 Project: 231828.0003.0000  
 Location: China Township, MI  
 Test Well: MW-16-04  
 Test Date: 4/13/16

AQUIFER DATA

Saturated Thickness: 23.5 ft

Anisotropy Ratio (Kz/Kr): 1.

WELL DATA (MW-16-04)

Initial Displacement: 1.064 ft  
 Total Well Penetration Depth: 109.9 ft  
 Casing Radius: 0.08333 ft

Static Water Column Height: 109.9 ft  
 Screen Length: 5. ft  
 Well Radius: 0.08333 ft

SOLUTION

Aquifer Model: Confined  
 K = 7.93E-5 cm/sec

Solution Method: Bowser-Rice  
 y0 = 0.7646 ft

MW-16-04 RISING HEAD SLUG TEST

Data Set: P:\...\MW-16-04\_OUT.aqt  
 Date: 05/22/17

Time: 13:42:08

PROJECT INFORMATION

**DESCRIPTION**

Cinders, fill  
Sandy topsoil  
Soft, brown & gray, silty Clay (CH)  
trace fine sand, high plasticity  
Stiff, brown, some fine sand

Very soft to soft, gray, silty Clay (CH-CL)

Firm, gray, sandy clay layer

Gray, silty Clay (CL) medium plasticity, 20% fine to coarse sand

Stiff, dark, gray clayey sand (SC)

Firm to stiff, gray, silty clay (CL), silt lenses  
Hard, some fine sand

Compact, gray, fine sand (SP)

silty fine sand (SM) 15% nonplastic fines

Compact, gray, very fine to coarse sand (SW)

Silty sand (SM) 15% nonplastic fines

Bottom of hole - Elevation - 451.4  
- Depth - 135.0 ft

This hole stopped at 135.0 ft. due to gas.

With casing at 110.0' no gas. Casing pulled to 57.0'. No gas. Pulled to 50.0', gas bubbling in hole. Capped hole and left for 48 hours. After 48 hours no gas (pocket only)

2-8-74 No gas  
2-11-74 Gas  
2-11-74 Pulled to 50.0', capped  
2-11-74 1400 hours removed cap (no gas)

82.5' - 107.0' used Gel to keep open

For Water Table information consult Section 4.1.3.

BELLE RIVER PLANT UNITS I & II  
SOIL CLASSIFICATION TESTS

FILE NO. 1255 DATE JAN. 74

### GRAIN SIZE DISTRIBUTION

U.S. STANDARD SIEVE SIZE

COBBLES	GRAVEL		SAND			SILT OR CLAY
	COARSE	FINE	COARSE	MEDIUM	FINE	

UNIFIED SOIL CLASSIFICATION SYSTEM

### PLASTICITY CHART (COHESIVE SOIL ONLY)

### MATERIAL SOURCE

IDENTIFICATION: SILTY CLAY (CL)  
 EXPLORATION: BORING 38  
 SAMPLE: 12  
 DEPTH: 54.1' TO 54.5'  
 SPECIFIC GRAVITY: USED 2.70

THE DETROIT EDISON COMPANY  
 BELLE RIVER PLANT UNITS I & II  
 SOIL CLASSIFICATION TESTS

C-610

FILE NO. 1255 DATE JAN 74
