RE: DTE Electric Company Comments on Proposed Decision: Proposed Denial of the CCR Part B Alternate Liner Demonstration Application, DTE Electric Belle River Power Plant Bottom Ash Ponds and Diversion Basin, China Township, Michigan  
Docket ID: EPA-HQ-OLEM-2021-0282; Sent via Regulations.gov and email

Dear Ms. Lloyd:

The DTE Electric Company (DTE) respectfully submits these comments to Docket EPA-HQ-OLEM-2021-0282 in response to the U.S. Environmental Protection Agency (EPA) Proposed Denial of the CCR Part B Alternate Liner Demonstration Applications for DTE Belle River Power Plant's Bottom Ash Basins and Diversion Basins (Proposed Decision). DTE appreciates EPA's commitment to move the needle on the Part B applications but strongly believes that the Applications should be approved based on the technical record and the attached comments. DTE has demonstrated through robust site characterization provided to the EPA and again provided in these comments, that the Bottom Ash Basins and Diversion Basin comply with the requirements of the CCR rule, are not impacting groundwater within the uppermost aquifer, and have the necessary site characteristics to be eligible to perform an Alternate Liner Demonstration.

DTE acknowledges the level of effort required to make well-informed reasoned decisions and appreciates EPA's time in reviewing the vast amount of data DTE has provided. DTE welcomes the opportunity to engage in discussions with the Agency regarding their review of this response and any other comments that are received in the docket.

Thank you for considering these comments. Should you have any questions, please do not hesitate to contact me ([shawn.patterson@dteenergy.com](mailto:shawn.patterson@dteenergy.com); 313-235-7720).

Sincerely,

A handwritten signature in black ink that reads "Shawn Patterson". The signature is fluid and cursive, with the first name "Shawn" being larger and more prominent than the last name "Patterson".

Shawn Patterson

**COMMENTS OF DTE ELECTRIC COMPANY ON EPA'S PROPOSED DENIAL OF THE CCR PART B ALTERNATE LINER DEMONSTRATION APPLICATIONS, DTE ELECTRIC, BELLE RIVER POWER PLANT, BOTTOM ASH BASINS AND DIVERSION BASIN, CHINA TWP, MICHIGAN**

Docket ID No. EPA-HQ-OLEM-2021-0282

## **I. Introduction**

DTE Electric Company (DTE Electric or DTE) is providing this response and comments on the U.S. Environmental Protection Agency's (EPA or Agency) proposed denial of the CCR Part B Alternate Liner Demonstration Applications for the DTE Electric Belle River Power Plant Bottom Ash Basins and Diversion Basin, China Township, Michigan (Proposed Decision), EPA Docket ID EPA-HQ-OLEM-2021-0282. This Proposed Decision comes more than two years after DTE's Applications for Alternate Liner Demonstrations for the Belle River Bottom Ash Basins and the Diversion Basin Coal Combustion Residuals (CCR) Units which were submitted to the Agency on November 30, 2020 (Applications).

DTE has carefully reviewed the Proposed Decision and it appears that EPA did not review all of the information available to them during the time of their review, most importantly the Preliminary Alternate Liner Demonstration reports (PALDs)<sup>1</sup> that were submitted to EPA on November 30, 2021. DTE has also identified many relevant facts about the facilities that were not considered or were misinterpreted. Lastly, the Proposed Decision goes beyond the standards for review of an application contained in the rule and EPA's guidance by (i) dismissing the certifications of the Qualified Professional Engineer which provides the basis for

compliance with the regulations, and (ii) introducing review criteria that do not follow the prospective nature of the applications.

The Belle River Power Plant Bottom Ash Basins and Diversion Basin (BRPP BABs and DB) are existing surface impoundments underlain by a clay-rich, consistently present, glacially-compacted geologic barrier that serves as a natural liner system. DTE submitted the Applications under Part B<sup>2</sup> to pursue the opportunity to demonstrate that the natural hydrogeological conditions unique to this site meet the alternative liner requirements set forth in the rule that would allow continued operation of the unit.

The Proposed Decision overlooks the significance of the conceptual site models and the unique hydrogeological setting present at these facilities with an abundance of natural clay-rich soils. These soils have a  $2.1 \times 10^{-8}$  centimeters per second (cm/s) to  $2.9 \times 10^{-8}$  cm/s hydraulic conductivity based on the available dataset provided in the Applications. EPA acknowledges in the Part B Preamble (at 72509), natural soils are capable of achieving the required effective hydraulic conductivities lower than  $1 \times 10^{-8}$  cm/s and/or on a case-by-case basis may exhibit an adequate thickness of low-conductivity soil that supports having somewhat higher soil conductivities throughout the soil column. This range of hydraulic conductivity of the glacially-compacted natural clay liner system is well below the threshold to be considered for an ALD as presented in the Part B Preamble (at 72509) where EPA also states “Regardless, a conductivity of  $1 \times 10^{-7}$  cm/s for the lowermost soil component of the liner, whether in isolation or beneath a geomembrane component, remains the absolute floor for any unit to even be considered for an alternate liner demonstration.” Yet, the EPA is proposing to deny the Applications on the basis of having hydraulic conductivities that are too high to meet the performance standards required by Part B.

The Proposed Decision also ignores the significant amount of site-specific characterization data provided in the PALDs that further confirms the conceptual site model and demonstrates that the clay is laterally continuous and is at a minimum over 80 feet thick, and as much as 120 feet thick (a minimum of greater than 26 times the clay liner thickness modeled in the 2014

Alternate Liner Demonstration Applications  
EPA–HQ–OLEM–2021–0282  
April 10, 2023

risk assessment of EPA's Regulatory Impact Analysis<sup>3</sup>). Further, several data interpretations are taken out of context to speculate various instances of potential historic non-compliance which are used as reasons to deny the Applications.

EPA also inappropriately dismissed the certifications of the qualified professional engineer (QPE) in finding that certain elements of DTE's groundwater monitoring programs do not meet the requirements of the CCR rule<sup>4</sup>, even though the facilities' QPE certified compliance with the requirements of the CCR rule. The CCR rule does not permit EPA to summarily reject the compliance certifications of QPEs as part of the Agency's Part B reviews. The Agency has made clear, both in the preamble of the CCR rule and the plain language of the regulatory text, that a QPE certification under the CCR rule is the regulatory mechanism for demonstrating compliance with the applicable technical standards.

Lastly, EPA's procedural implementation of the rule created a paradox that effectively foreclosed the submission of an ALD due to the passage of regulatory deadlines during EPA's extended review period. The CCR Part B Rule required the Agency to issue a final decision on an application was within 60 days of receiving a complete application per § 257.71(d)(2)(iii). The Part B rule contemplates that once an owner/operator receives approval of its application, it would proceed to submit an alternative liner demonstration by November 30, 2021 (40 C.F.R. 257.7(d)(2)(i)). However, DTE did not receive the Proposed Decision until 786 days had passed – well beyond the deadline for filing an ALD. It is unclear, but EPA appears to have chosen to deny the Applications in part due to lack of data while ignoring the PALD on the basis that it was received prior to approval of DTE's Applications. But had DTE followed the procedure as contemplated by the rule, and had EPA approved the Applications, the Agency would have foreclosed the ability to submit an ALD because the deadline in 40 C.F.R. 257.7(d)(2)(i) had passed putting DTE in a situation where compliance could never legally be demonstrated.

These comments have been prepared to provide clarification and additional information to resolve EPA's comments and address uncertainties expressed by the Agency in the Proposed Decision. DTE anticipates that the additional information provided herein will be beneficial in improving the Agency's understanding of the site and trusts that the EPA reconsiders their Proposed Decision.

## **II. Background**

DTE Energy is a diversified energy company, headquartered in Detroit, Michigan, that is involved in the development and management of energy-related businesses and services nationwide. Our operating units include an electric utility (DTE Electric) and a natural gas utility (DTE Gas) which provide electric and/or gas services to residential, business, and industrial customers throughout Michigan. The DTE portfolio also includes non-utility energy businesses focused on power generation and industrial projects, natural gas pipelines, gathering and storage, and energy marketing and trading.

DTE Electric has enjoyed powering homes and businesses in Southeastern Michigan for well over a century. DTE Electric is the largest electric utility in Michigan and one of the largest in the nation, generating and distributing electricity to 2.3 million residential, commercial and industrial customers. With an 11,840 megawatt system capacity, DTE uses coal, nuclear fuel, natural gas, hydroelectric pumped storage and renewable sources to generate electrical output for the benefit of its customers. DTE Electric owns and operates approximately 31,000 miles of overhead distribution lines and 16,000 miles of underground distribution lines to a service territory that spans 7,600 square miles.

The BRPP is a 1,270 MW (summer rated capacity) baseload coal-fired power plant in St. Clair County, Michigan and has two units in total. DTE Electric is the majority owner of Belle River, owning 81.39% of the plant, with Michigan Public Power Agency (MPPA) owning the remainder.

The BABs are designed to manage sluiced bottom ash and have been in operation since the BRPP began operation in 1984. The BRPP BABs are two adjacent physical sedimentation basins that are slightly raised CCR surface impoundments referred to as the North and South BABs, located north of the BRPP. The BABs receive sluiced bottom ash and other process flow water from the power plant. Discharge water from each BAB flows over an

## DTE Electric Comments

EPA-HQ-OLEM-2021-0282

April 10, 2023

outlet weir that gravity flows to a site storm water conveyance network of ditches and pipes, then flows into the DB. The North and South BABs are located north of the BRPP main building and run roughly east to west approximately 420 feet long by 120 feet wide and are approximately 0.88 and 0.87 acres, respectively (See Figure 2 in the BABs Application).

The DB is an incised CCR surface impoundment located west of the BRPP. Water flows into the DB from the North and South BABs through a network of pipes and ditches. The DB discharges to the St. Clair River with other site wastewater in accordance with a National Pollution Discharge Elimination System (NPDES) permit. The DB has an approximately 300-foot-long entrance channel that connects to the main portion of the basin that runs approximately north-south. The main portion of the DB is approximately 400 feet long by approximately 120 feet wide and the DB is approximately 1.55 acres (See Figure 2 in the DB Application).

In 2020, Michigan's solid waste statute was amended to align with the federal CCR rule, including a groundwater monitoring program. Amendments to the monitoring system were made to align with the State solid waste rules/statutes, and a new Solid Waste Operating License that applies to both the BABs and the DB was issued by the Michigan Department of Environment, Great Lakes, and Energy (EGLE) that approved the current groundwater monitoring networks. DTE continues to operate and maintain the BRPP BABs and DB in accordance with their operating license and solid waste statutes/rules. Documents demonstrating DTE's compliance with applicable State solid waste rules and the CCR rule for the BRPP BABs and DB are posted on DTE's CCR rule compliance data and information website<sup>5</sup>, and/or in the facility operating records. This includes documents required to be certified by QPEs consistent with the self-implementing nature of the CCR rule.

#### **A. History of Conceptual Site Model:**

The BRPP BABs and DB were constructed in the early 1980s. Over the past 40 plus years, DTE has performed geologic studies and reviewed publicly available regional reports to characterize the site hydrogeological conditions, develop the conceptual site model, and

## DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

support demonstrations that DTE has made to state regulators and the EPA, regarding the site-specific geology and the appropriateness of the groundwater monitoring programs prepared consistent with applicable State and Federal regulations. Some noteworthy studies and key reports include:

- A 2007 report by Beth Apple and Howard Reeves and titled "Summary of Hydrogeologic Conditions by County for the State of Michigan", U.S Geological Survey Open-File Report 2007-1236. Information from this report was utilized by DTE to inform the development of the site conceptual model, and to support the development of the Applications.
- A 1976 report by Bechtel titled "Subsurface Investigation and Foundation Report", The Detroit Edison Company, Belle River Units 1 & 2 containing approximately 74 soil boring logs and fence diagrams, cross sections and soil properties measurements for work performed from 1973 to 1975 to provide soil data across the planned area of the BRPP in support of the design of the BRPP. This report predated any solid waste regulation of ash disposal facilities by the State of Michigan. Information from this report was utilized by DTE to inform the development of the site conceptual model, to support the development of the Part B Applications and was included in the Applications.
- A 2018 report by TRC titled "Natural Clay Liner Equivalency Evaluation Report" that used information from regional geologic reports and existing site data to assess whether the natural soils below 6 CCR surface impoundments two of which were the BABs and DB CCR units, are performing equivalently to a composite liner using recognized and generally accepted good engineering practices. The report concluded that the natural clay liners at each of the evaluated sites are more protective than a single composite liner system and meet the RCRA protectiveness standard "does not pose a reasonable probability of adverse effects on health or the environment." This report was included in the Applications.
- The 2021 BAB and DB PALDs, prepared by Geosyntec in accordance with § 257.71(d)(1)(ii), are the latest demonstrations executed by DTE that similarly conclude the natural clay liner present beneath the BABs and DB is one of the several types of natural soil liners described by EPA in the Part B Preamble that is naturally protective, as it has undergone glacial compaction and achieves a sufficiently and consistently low hydraulic conductivity that effectively controls leachate within the BRPP BABs and DB

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

across the entire site. Thirty-four boring locations were investigated as part of these demonstrations, including a rigorous laboratory study was implemented, lasting nearly two years, and a robust mathematical model developed in accordance with the requirements of the Part B rule that further reduces any uncertainty in the heterogeneity of the natural clay liner present at the site. The PALDs are substantially complete demonstrations, but titled preliminary due to the long time it takes to conduct the ASTM D7100 laboratory testing, which is due to the significantly low-conductivity nature of the clay that can take up to well over a year to reach the termination criteria. Consistent with previous investigations and studies performed at the site, the PALDs conclude that the underlying natural clay liner is continuously present across the site and meets the protectiveness standard of RCRA Subtitle D, and more specifically there is no reasonable probability that water from the BABs or DB will cause releases to groundwater that will exceed the groundwater protection standards (GWPS) at the waste boundary over the projected active life of the unit. DTE submitted the PALDs to EPA on November 30, 2021, in accordance with § 257.71(d)(1)(ii), well in advance of the Proposed Decision, however, based on the Agency's comments, it does not appear that EPA reviewed the content of the demonstrations. The BAB and DB PALDs are included in this letter as Attachment A.

- The final ALDs prepared by Geosyntec were completed in 2023. Since the submittal of the PALDs in 2021, the analysis of the hydraulic conductivity compatibility samples required under § 257.71(d)(1)(ii)(B)(2) were terminated in December 2022, after running for almost two years, due to the very low hydraulic conductivity of the samples. To that end, DTE is providing the updated final ALDs as an attachment to this response and summarizing the information in this response to provide the additional technical details from the ALDs. The results from the final ALDs are also incorporated below in this response to further address the uncertainty and misunderstanding expressed by EPA in the Proposed Decision. Copies of the final ALDs are included in Attachment B of this letter.
- Finally, in 2022/2023 DTE performed a supplemental aquifer characterization investigation to further characterize the site conditions and aquifer properties using a combination of groundwater geochemical, stable isotope, and radiogenic isotope analysis. This characterization also included an in-depth analysis of existing site data

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

collected through 2022 from the BABs and DB CCR units. The TRC "Additional Uppermost Aquifer Characterization Study" reports (Aquifer Characterization Studies) performed by TRC provide even more site-specific data that supports the conceptual site model for the site and further documents that the aquifer remains unaffected by the BAB and DB CCR management activities over the active life of the BABs and DB. The Aquifer Characterization Studies further substantiate site compliance and the efficacy of the Alternate Source Demonstration(s) at the BABs CCR unit and further demonstrates the protectiveness of the natural clay liner through a series of in-depth geochemical and isotopic data analysis, including general chemistry, ionic speciation, mineral saturation, stable and radiogenic isotopes in combination with advanced statistical analysis that affirmatively demonstrates that the uppermost aquifer is not in communication with the CCR unit water, groundwater geochemistry in the uppermost aquifer is reflective of the geogenic natural environmental conditions, and is therefore unaffected by the BRPP BABs and DB CCR units. The Aquifer Characterization Studies are included in Attachment C of this letter.

In summary, DTE has been monitoring and operating the BRPP BABs and DB for decades, and has amassed extensive subsurface data at the BRPP to evaluate the long-demonstrated effectiveness of clay underlying the BRPP BABs and DB. The significant amount of site characterization data substantiates that the aquifer remains unaffected by the CCR units and demonstrates the protectiveness of the glacially-compacted natural clay liner system. This wealth of information was provided to EPA in a timely fashion and, upon review, would suggest a different conclusion in this matter.

Since promulgation of the 2015 CCR rule, with active involvement and required certifications from QPEs, DTE evaluated siting and design requirements, confirmed that the unit is structurally sound, conformed to the operating criteria, established groundwater monitoring networks, statistical plans, as required by the self-implementing CCR rule. Many of these requirements enacted under the CCR rule were already being implemented in cooperation with state regulators as part of ongoing state program compliance.

## DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

DTE continues to operate its CCR units in a manner that meets or exceeds all State and Federal requirements. DTE developed and manages a CCR program that is both protective of human health and the environment, and compliant with the requirements of the CCR rule as they are written, in the context of the unique site-specific conditions at BRPP.

### **III. Part B Purpose and Intent**

The Part B amendment to the CCR rule was developed to allow facilities with environmentally protective and impermeable hydrogeological characteristics to demonstrate that their existing naturally clay-lined systems perform as well as, or better than composite liner systems to ensure there is no reasonable probability of adverse effects to human health and the environment. The 2015 CCR rule was developed as a one-size-fits-all program that did not originally contemplate forced closure for units with naturally occurring conditions that are as protective as synthetically lined CCR surface impoundments. This changed with promulgation of the Part A rule as a result of the 2018 DC Circuit Court USWAG decision<sup>6</sup>. Consequent, this could have resulted in unnecessary closure or retrofitting of protective natural clay lined surface impoundments where there is no reasonable potential for migration of CCR constituents to groundwater due to the natural subsurface conditions. The Part B amendment offers a modification to the CCR rule to account for these uncommon and unique, yet protective, circumstances by including a procedure for facilities to request approval to operate an existing CCR surface impoundment with an alternate natural clay liner.

Additionally, the 2015 CCR rule was also designed to be self-implementing, requiring certification from qualified professional engineers (QPEs) and, in some cases, state regulatory agencies, in place of direct oversight from EPA. As a result, the groundwater monitoring requirements had to be universally applied to all facilities subject to the CCR rule, including establishment of monitoring programs for surface impoundments at facilities with unique hydrogeological conditions that do not necessarily meet the “one-size fits all” monitoring standards of the CCR rule, void of any dialogue with the EPA. While not common, several of these sites with natural clay liners may be otherwise eligible for a no-migration demonstration under other state-administered or federal RCRA programs. This is the case for the BRPP BABS and DB.

Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

The Part B amendment offers a modification to the CCR rule to account for these uncommon and unique, yet protective, circumstances by including a procedure for facilities to request approval to operate an existing CCR surface impoundment with an alternate natural clay liner. The Part B rule provides a means to allow sites under these special conditions to continue to operate while being protective of human health and the environment. EPA recognizes with the enactment of Part B that the potential exists for facilities to successfully demonstrate that naturally compacted clay can serve as a protective liner system under certain conditions. The purpose of the Part B application (step 1) is to provide the necessary site information under the rule to show the facility exhibits these unique circumstances. An approved Part B application affords the opportunity to make the robust alternate liner demonstration (ALD) (step 2) by performing a significant amount of field investigation and data analysis to confirm that the continued operation of the unlined surface impoundment presents no reasonable probability of adverse effects to human health or the environment within the operational life of the CCR unit.

### **IV. Groundwater Has Not Been Impacted by the BRPP BABs and DB**

DTE is confident that the BRPP BABs and DB groundwater monitoring programs appropriately consider the site-specific hydrogeologic conditions present at the site and accurately represents the quality of groundwater passing the downgradient boundary of the units. The data provided to EPA in the Applications met the requirements of the rule, and clearly show that the BRPP BABs and DB groundwater monitoring programs appropriately remain in detection monitoring. To align the groundwater monitoring programs with the conceptual site model, the basis of the groundwater monitoring programs hinge on the key premise that the uppermost aquifer have not been affected by operation of the BRPP BABs and DB. This approach is substantiated with data that is further discussed in these comments.

DTE implemented BABs and DB Aquifer Characterization Studies (Attachment C) to further characterize the site conditions (including separation of the uppermost aquifer from the BABs and DB) and aquifer properties using a combination of geochemical, stable isotope, and radiogenic isotope analysis, with additional in-depth analysis that provides even more site-specific data that supports the conceptual site model for the site and further upholds the underlying premise that the uppermost aquifer is not in communication with the BABs or

## DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

the DB and remains unaffected by the CCR units and has remained as such over the active life of the BABs and DB. The Additional Aquifer Characterization Study reports (Aquifer Characterization Studies) further substantiate site compliance and the efficacy of the BABs Alternate Source Demonstrations and further demonstrate the protectiveness of the natural clay liner.

The Aquifer Characterization Studies demonstrate a distinct difference in chemical compositions between the groundwater underlying the unit, the pore water in contact with ash within the BABs and DB, and the surface water in the nearby surface water body (St. Clair River). Fundamentally, groundwater chemistry is influenced by the various minerals and gases that are available to react with the water as it travels through the subsurface – through pores and fractures in rock or sediment. Their mere presence in groundwater does not indicate that a release from a CCR unit has occurred. The results of the groundwater study demonstrate with additional site-specific and quantifiable evidence that the uppermost aquifer has not been impacted by the operation of the BABs and DB since operations began nearly 40 years ago, and that the source of the constituents observed in the uppermost aquifer are geogenic in nature.

The uppermost aquifer, as defined in 40 CFR §257.53, underlying the BABs CCR unit consists of saturated sand and the uppermost aquifer underlying the DB CCR unit consists of saturated silt present beneath thick laterally contiguous glacially-compacted natural clay liner system<sup>7</sup> that serves as a natural confining hydraulic barrier that isolates the underlying uppermost aquifer. The BABs and DB CCR units have a minimum of 82 feet and 120 feet, respectively of glacially-compacted natural clay liner systems separating the bottom of the BABs and DB from the uppermost aquifer. The overlying low-permeability clay that separates the BABs and DB from the uppermost aquifer has a hydraulic conductivity of  $4.4 \times 10^{-9}$  to  $2.1 \times 10^{-8}$  cm/s<sup>8</sup>, exceeding the requirements of the design criteria for the lower component of a composite liner. These hydrogeological characteristics align with the types of natural liners described in the Part B Preamble (at 72509) that EPA believes have the potential for facilities to successfully demonstrate that naturally compacted soil can be

---

<sup>7</sup> The continental glaciers over Michigan were about one-mile thick. <https://www.noaa.gov/education/resource-collections/freshwater/great-lakes-ecoregion> dated February 1, 2019

<sup>8</sup> April 2023 BABs and DB final ALDs page 3-3

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

protective, one of which has undergone glacial compaction, “whereby stress from the weight and flow of the glacier compressed the naturally occurring soil”. The lateral continuity, thickness, and consistently low permeability of the glacially-compacted natural clay liner system underlying the BABs and DB CCR units as demonstrated in the ALDs make these facilities well qualified for Part B demonstrations.

The PALDs, the final ALDs, and the Aquifer Characterization Studies provide additional detailed site information that further substantiates the conceptual site model at the site and the BRPP ASDs, and further verifies that the BABs and DB have not impacted groundwater.

The BABs and DB qualify for ALD Applications approval because continued compliance with the groundwater requirements set forth in §§ 257.93 through 257.94 is demonstrated, and the BABs and DB remain in detection monitoring in accordance with the provisions under § 257.71(d)(1)(i)(B)(2). Given the highly favorable hydrogeological conditions that occur naturally at the site, it is no surprise that groundwater monitoring data generated pursuant to the CCR rule shows that the BABs and DB are not impacting groundwater quality. As presented in the Applications, and discussed further below in this response, the facilities appropriately remain in detection monitoring in accordance with § 257.94 of the CCR rule, as discussed at length throughout this response.

## **V. The QPE’s Certification was Wrongly Dismissed**

The CCR rule is self-implementing in most states, including Michigan, and relies on QPE certification from qualified engineering practitioners to ensure compliance with the regulations. The aspects of the CCR program that require certifications are explicitly stated throughout the CCR rule. Certification of compliance is to be determined by a qualified professional utilizing site-specific data. For example, the design of the monitoring system relies on site-specific information and defers to PE certification for approval. Further, 40 C.F.R. § 257.91(f) requires “[t]he owner or operator must obtain a certification from a qualified professional engineer stating that the groundwater monitoring system has been designed and constructed to meet the requirements of this section.” That certification provides the means for compliance with 40 C.F.R. § 257.91(f).

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

EPA inappropriately proposes to find that elements of DTE's groundwater monitoring program do not meet the requirements of the CCR rule, even though the facilities' QPE certified compliance with the requirements of the CCR rule. The CCR rule does not permit EPA to summarily reject the compliance certifications of QPEs as part of the Agency's Part B reviews. While it is possible that a technical disagreement between EPA and the QPE may result in future modifications to a facility's operations, this disagreement cannot be the basis for finding that an owner/operator is not in compliance with applicable CCR rules, when they have relied upon a QPE certification in accordance with the CCR rule. This is because reliance on a QPE certification is how, pursuant to the CCR rule, a facility is required to demonstrate compliance.

The Agency has made clear, both in the preamble of the CCR rule and the plain language of the regulatory text, that a QPE certification under the CCR rule is the regulatory mechanism for demonstrating compliance with the applicable technical standards. The Part B rule did not change this regulatory framework and there is no requirement that EPA independently review a facility's compliance. Rather, the rule clearly places the burden on the applicant to demonstrate compliance. DTE has made this demonstration by submitting certain documentation to EPA, including a certification stating that the facility is in compliance. If the rule required EPA to independently evaluate all technical materials, there would be no reason to require this compliance certification in the first instance. By submitting the required documentation, the regulatory presumption is that the facility is in compliance.

To be clear, DTE is not claiming that EPA does not have statutory authority to enforce the CCR rule. That authority was clearly granted to the Agency in 2016 with the passage of the Water Infrastructure Improvements for the Nation ("WIIN") Act. But the WIIN Act did not change the rule's framework for demonstrating compliance through QPE certifications. Nor are EPA's Part B reviews done pursuant to its enforcement authority under RCRA § 3008. In fact, EPA explicitly stated that the Part B compliance determinations are made solely for purposes of Part B demonstrations and are not relevant in any other context. Thus, until EPA successfully pursues enforcement against a facility under its § 3008 enforcement authority, a facility cannot be found in noncompliance when it has obtained the requisite compliance certification from a QPE.

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

Again, while subsequent disagreement between EPA and the QPE may result in the facility possibly amending certain CCR compliance plans or documents, it cannot be the basis for finding a facility in noncompliance with the applicable standards without an adjudication made through the statutory enforcement process. And even if, for purposes of argument, EPA could overrule the compliance certification of a QPE, EPA must have a rational basis for doing so. EPA's obligation to engage in reasoned decision-making demands more than simply asserting, without pointing to any specific error by the QPE, that the facility is not in compliance with the CCR rule.

## **VI. The Part B Rule Contains Timelines for Implementation That Were Not Followed Depriving DTE of an Opportunity for Meaningful Consideration of Its Application and the Ability to Submit an ALD**

The CCR Part B Final Rule was published on November 12, 2020, and provided applicants only 18 days (November 30, 2020) to submit a completed application, for facilities to request approval to use an alternate liner for CCR surface impoundments per 40 C.F.R. § 257.71(d). 40 C.F.R. § 257.71(d)(2)(iii)(C) states that "EPA will publish a proposed decision on complete applications in a docket on *www.regulations.gov* for a 20-day comment period. After consideration of the comments, EPA will issue its decision on the application within sixty days of receiving a complete application." An applicant must submit its demonstration by November 30, 2021.

DTE submitted its Applications on time on November 30, 2020, and received notification that the Applications were administratively complete on January 11, 2022 – 6 weeks after the regulatory requirement for submission of an ALD. The letter did not extend the deadline for ALD submissions beyond the 2021 deadline, so unless an owner/operator preemptively submitted a demonstration without approval, EPA had foreclosed the opportunity to do so.

In an attempt to preserve its right to file the ALDs, DTE submitted an extension request on September 1, 2021, and an update to the extension request on September 1, 2022, under 40 C.F.R. § 257.71(d)(2)(ii)(A). EPA never responded to the extension requests, and therefore, the preliminary results of the demonstration were submitted to EPA on November 30, 2021, as required by 40 C.F.R. § 257.71(d)(2)(ii). In addition to fulfilling the

## DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA–HQ–OLEM–2021–0282  
April 10, 2023

requirements of the alternate liner demonstration under 40 C.F.R. § 257.71(d)(1)(ii), the PALDs included important information to support DTE's Applications, but for reasons unknown to DTE, the PALDs were not considered in the Proposed Decision.

In EPA's January 11, 2022, completeness determination letter, the Agency states that the Application contains sufficient information for the Agency to evaluate the merits of the Application. However, EPA has proposed to deny the Applications, in part on the basis that the Applications did not provide sufficient information, which is contradictory to the completeness determination. Additionally, 40 C.F.R. § 257.71(d)(2)(iii) states that "EPA will evaluate the application and may request additional information not required as part of the application as necessary to complete its review." Much of the information EPA suggests is missing is included in the PALDs and could have been referenced during EPA's extended review period. Moreover, DTE would have welcomed the opportunity to provide additional information.

DTE is providing an update to each of the PALDs (the final ALDs) through this comment package as Attachment B to emphasize the relevancy of the comprehensive site characterization in the Agency's final decision making. The final ALDs include updated analytical data from compatibility tests that were ran through December 2022, which were used to confirm that the model results in the PALDs are accurate. The final ALDs continue to demonstrate that there is no reasonable probability that water from the BABs or DB will cause an exceedance of the groundwater protection standards outside of the BABs or DB.

### **VII. Active Life of the Bottom Ash Basins and Diversion Basin**

In order for the BRPP to continue operation and provide electric service to Southeast Michigan, the BABs must continue to receive sluiced bottom ash until such time that the two generating units at the power plant are converted to natural gas power generation by 2026. These plans are currently under review by the Michigan Public Service Commission.

### **VIII. Demonstrated Compliance with the CCR rule**

DTE has prepared the following discussion to further highlight the hydrogeological characteristics that make these facilities uniquely qualified for Part B demonstrations. The information presented below demonstrates that compliance with the Part B Rule has been and

## DTE Electric Comments

EPA-HQ-OLEM-2021-0282  
April 10, 2023

continues to be met at the DB and BABs and is meant to provide additional clarification to help resolve any misinterpretations or uncertainties expressed by the Agency in the Proposed Decision to deny the Application.

### **A. Documentation of Groundwater Monitoring Network Compliance**

In the Proposed Decision, EPA alleges that the information required under 40 C.F.R. § 257.71(d)(1)(i)(B)(7) is not included in the BABs and DB Applications. The design and placement of the monitoring well networks are well-documented in the Applications and narratives are provided on pages 8 and 9 in the Applications that speak to the well network designs along with supporting information and reports detailing the established monitoring well networks in Appendix B. Additional supporting information regarding well locations, site geology (including the continuous presence of clay underlying the BABs and DB), and groundwater flow potential are provided in Figures 2 through 10 of the Applications. The information and narratives provided in the Applications along with the QPE certification of the well networks comply with 40 C.F.R. § 257.91 and demonstrate a thorough understanding of site hydrogeology and the potential for the impoundments to impact the groundwater flow.

The information provided in the Applications includes all of the information required under 40 C.F.R. § 257.71(d)(1)(i)(B)(7) as follows:

- Map(s) of groundwater monitoring well locations in relation to the CCR unit(s) that depict the elevation of the potentiometric surface and the direction(s) of groundwater flow across the site;
  - Provided in the Applications Figures 6-10 Groundwater Potentiometric Surface Maps from September 2017 through September 2019, and additionally in the 2017 through 2019 Annual Groundwater Monitoring Reports in Applications Appendix C, D, and E);
- Well construction diagrams and drilling logs for all groundwater monitoring wells;
  - Provided in Applications Appendix B – Groundwater Monitoring Systems Summary Reports;

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

- Maps that characterize the direction of groundwater flow accounting for temporal variations;
  - Provided in the Applications Figures 6-10 Groundwater Potentiometric Surface Maps from September 2017 through September 2019, and additionally in the 2017 through 2019 Annual Groundwater Monitoring Reports in Applications Appendix C, D, and F); and
- Any other data and analyses the owner or operator of the CCR surface impoundment relied upon when determining the design and location of the groundwater monitoring network.
  - Key historical reports and other information relied upon to develop the monitoring networks are included in the Applications in the Appendices including Appendix K – Subsurface Investigation and Foundation Report, Belle River Units 1&2, Bechtel, 1976.

#### **1. Monitoring System Meets 40 C.F.R. § 257.91(a)(1)**

The BABs and DB monitoring systems meet the performance standard set forth in 40 C.F.R §257.91(a)(1)(ii). 40 C.F.R § 257.91(a)(1) does not explicitly require that all background concentrations be established in hydraulically upgradient wells. Similar to both the Subtitle C and Subtitle D RCRA regulations, the CCR Rule allows for a determination that background quality may include sampling of wells not hydraulically upgradient of the waste management area, but is not required. Specifically, 40 C.F.R § 257.91(a)(1)(ii) allows the determination of background using wells that are not hydraulically upgradient of the CCR management area that “provide an indication of background groundwater quality that is as representative or more representative than that provided by the upgradient wells.” As such, 40 C.F.R § 257.91(a)(1)(ii) is inclusive of situations where intrawell analysis is appropriate and accounts for the use of downgradient wells to determine background. The reasoning that the background at the downgradient wells is more representative than the upgradient wells ties into the same reasoning that intrawell methods are appropriate at this site. This is largely related to the spatial variability observed throughout the well networks, in combination with the extremely long travel times for groundwater to flow across the base of the CCR units. A

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

more thorough discussion of the reasoning is provided below on the intrawell discussion (see Section VIII.B.1.a).

EPA's states that "[t]he CCR regulations require development of a groundwater monitoring network that will identify the background level of contamination in the uppermost aquifer upgradient of a CCR unit, so that those levels can be compared with the contaminant levels in the wells downgradient of the CCR unit after the groundwater has flowed beneath it. See 2015 CCR rule preamble at 80 FR 21302, 21399-400."<sup>9</sup> While it is well understood that the purpose of detection monitoring is to assess background groundwater quality and use it to compare to groundwater quality after it has passed beneath the CCR unit, we cannot corroborate EPA's reference to the Preamble that implies all groundwater up- and downgradient is contaminated and that the purpose of monitoring is to compare the difference in contamination levels in up- and downgradient wells. Although that may be the case in some instances where there are other sources impacting groundwater quality prior to passing beneath the CCR unit, EPA's bias toward assuming that all groundwater being monitored is "contaminated" is grossly overstated. In contrast, the EPA's Unified Guidance states that "[u]nits under detection monitoring are initially presumed not to be contributing a release to the groundwater unless demonstrated otherwise."<sup>10</sup>

From the onset of monitoring at the BABs and DB, a myriad of data from historical site information, regional water quality, and more recent data collected as part of implementation of the CCR rule, indicates that the uppermost aquifer beneath these two units is unaffected by CCR operations. Therefore, the foundational premise of the detection monitoring program that the aquifer remains unaffected by the BAB and DB CCR management activities (i.e. the underlying clay is protective) has been met, and, as such, the well networks are designed to detect a potential future release per 40 C.F.R § 257.91. There is no mechanism for groundwater in the upgradient wells to be affected by a release from the CCR units through the clay. It would require travel times that far exceed the timeframe in which the impoundments have been in service for CCR-affected

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

water to get through at least 82 feet (BABs) or 120 feet (DB) of clay-rich soil as demonstrated in the Natural Clay Liner Equivalency Evaluation Report, DTE Electric and Consumers Energy Company Six Southeast Michigan Coal Combustion Residual Units, December 2018 (Liner Equivalency Report) (BABs and DB Applications Appendix A), BABs and DB PALDs (submitted to EPA November 30, 2021) (Attachment A), and the final ALDs (Attachment B).

In addition, in December 2022 water samples collected from the water within the BABs and DB and from the groundwater monitoring system wells for additional aquifer characterization, documented within the BABs and DB Aquifer Characterization Studies (Attachment C), provide additional data substantiating that the uppermost aquifer is unaffected by CCR operations and that groundwater at all monitoring wells are not in communication with the CCR in the BABs or the DB.

Specifically, they substantiate the site conceptual model developed for the site at the early stages of the monitoring program, affirm that the uppermost aquifer remains unaffected by the facility, and further demonstrate that the BABs and DB are not in hydraulic communication with the uppermost aquifer, as provided in the following additional lines of evidence:

- Groundwater geochemistry is reflective of the natural environmental conditions and is influenced by the interaction of aquifer materials with various minerals, gases, and dissolved-phase constituents that are available to react with the water as it travels through the subsurface, including the presence of Appendix III concentrations in groundwater;
- Trilinear Diagrams demonstrate that the BABs and DB geochemical composition is very different than the groundwater in the uppermost aquifer;
- Stable isotopes within uppermost aquifer groundwater are consistent across all wells within the monitoring systems and are significantly different than the isotopic signatures of the CCR-contact water in the BABs and DB;
- Tritium data clearly shows that the groundwater within the uppermost aquifer groundwater pre-dates the time that the BABs and DB entered service; and

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

- Principle Component Analysis and Linear Discriminant Analysis of 2016 to 2022 Appendix III groundwater data for the BABs and DB demonstrated that the uppermost aquifer groundwater at the BABs and DB and their respective CCR units water are significantly different with a 95% confidence level. This is another line of evidence that the uppermost aquifer groundwater is not in communication with the BABs and DB CCR units water.

As such, there is a considerable amount of site characterization data that demonstrate these “background” wells have not been affected and that the groundwater samples collected from the monitoring systems are representative of natural background conditions.

## **2. Groundwater Monitoring System Designs are Adequate**

Regulation 40 C.F.R. § 257.91(b) requires that the monitoring system design be determined based on site-specific technical information. 40 C.F.R. §§ 257.91(b)(1) and (2) specify that the technical information must include thorough characterization of: aquifer thickness, groundwater flow rates and directions, seasonal fluctuations in groundwater flow; saturated and unsaturated geological units and fill materials overlying the uppermost aquifer; materials comprising the uppermost aquifer; and materials comprising the confining unit defining the lower boundary of the uppermost aquifer, including, but not limited to, thickness, stratigraphy, lithology, hydraulic conductivities, porosities, and effective porosities. The regulations do not prescribe the exact number, location, and depth of monitoring wells needed to achieve the general performance standard.

The Applications, PE certifications, and operating records include detailed technical information used to design the groundwater monitoring system including the key site-specific information (e.g. boring logs, well construction diagrams, water level data, groundwater flow direction, etc.) for the monitoring well network. The November 2021 preliminary ALDs, that have been in EPA’s possession since November 2021, further provide a voluminous amount of site characterization data, confirms the conceptual site model, and speaks to the adequate characterization of the site hydrogeology and heterogeneity.

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

Per the rule, the design of the monitoring system relies on professional judgement based on site-specific technical information and defers to PE certification for approval. Specifically, 40 C.F.R. § 257.91(f) requires “[t]he owner or operator must obtain a certification from a qualified professional engineer stating that the groundwater monitoring system has been designed and constructed to meet the requirements of this section.” EPA’s Preamble discussion states: “[f]or the final rule, EPA has developed a groundwater monitoring program that is flexible and allows facilities to design a system that accounts for site-specific conditions within specific parameters. The final rule establishes an overall performance standard that the system must meet, lays out the minimum requirements of an effective system, and requires the owner or operator to design a system that achieves that overall performance standard based on a full characterization of site conditions.”<sup>11</sup> Nevertheless, working within these constraints the rule specifically allows the qualified PE to design a system that accounts for site conditions within the parameters of the minimum technical criteria, and EPA even added language to the regulation that expressly clarifies this. The Agency has made clear, both in the preamble of the CCR rule and the plain language of the regulatory text, that a QPE certification under the CCR rule is the regulatory mechanism for demonstrating compliance with the applicable technical standards.

The BABs groundwater monitoring system consists of a total of five monitoring wells distributed along the BABs perimeter (MW-16-01 through MW-16-04 and MW-16-09) except in the southeast portion of the BABs perimeter where no uppermost aquifer was encountered, that are representative of background hydraulically upgradient although given there is not a clear groundwater flow direction it is difficult to determine which wells are hydraulically upgradient. The DB groundwater monitoring system consists of a total of six monitoring wells distributed along the DB perimeter, including three upgradient wells (MW-16-06, MW-16-07 and MW-16-08) that are representative of background hydraulically upgradient from the DB, and three downgradient wells (MW-16-05, MW-16-10, and MW-16-11A).

---

<sup>11</sup> Preamble at 21397-21398.

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

This distribution of wells within each of these monitoring systems allows groundwater quality to be monitored around the perimeter of each of the CCR units, provides a comprehensive view of groundwater flow direction and rates (where present) across the footprint of the entire CCR unit, allows adequate collection of background data upgradient, downgradient, and side gradient of the CCR unit, and facilitates assessment of any spatial variability in groundwater geochemistry across the uppermost aquifer beneath the footprint of each unit. The monitoring wells located around the perimeter of the BABs and DB have been selected to serve as both background and downgradient monitoring wells using intrawell statistical methods (discussed in more detail below in Section VIII.B.1.a) and provide increased protection by having downgradient monitoring wells distributed around the perimeter of the BAB.<sup>12</sup>

In determining specific placement of wells, the areas immediately around the berms at the BAB and around the DB were limited due to very soft soils with a series of ditches, etc. that restricted access to install the monitoring wells and also ensure that the monitoring well locations could safely be accessed during monitoring. For the DB, monitoring wells needed to be located outside of the third-party railroad and associated right of way (referred to by EPA as a "roadway" in the Proposed Decision p. 16). This resulted in monitoring wells MW-16-05, MW-16-10, and MW-16-11/MW-16-11A being installed to the west of the railroad and its associated right of way. The safety considerations of working in the railway in combination with the time needed to procure access to drill in the rail right of way did not conform with the timing constraints of 40 C.F.R. § 257.90(b), therefore, wells were installed as close as feasible to the CCR unit. Recall the timeline to get the monitoring well networks installed and to begin background groundwater sampling was very tight to initiate detection monitoring by October 17, 2017.

In addition to physical barriers and safety considerations, the monitoring system design was developed using the site's hydrogeological considerations. Aquifer characteristics are one of the key considerations in designing a monitoring system, such as hydraulic conductivity, hydraulic gradient, groundwater flow direction, aquifer heterogeneity, etc.

---

<sup>12</sup> Application, p. 8-9.

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin

Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

Diversion Basin Aquifer Characteristics:

- As detailed in the Application,<sup>13</sup> the BRPP DB CCR Unit is underlain by more than 120 feet of unconsolidated sediments, with the lower confining Bedford Shale generally encountered from 135 to 145 feet below ground surface (bgs). In general, the BRPP DB CCR Unit is underlain by at least 120 feet of laterally extensive low hydraulic conductivity clay-rich deposits. The clay-rich till is then underlain by two to seven feet of silt between the till and the underlying shale bedrock (not an aquifer) confining unit (Application Figures 3-5). Although the encountered zone of saturation within the silt just above the bedrock interface did not yield significant groundwater, it was conservatively interpreted as the uppermost saturated zone (the uppermost aquifer). Although the hydraulic conductivity was low, it exhibited a much higher conductivity than the clay-rich soils between the bottom of the basin and the monitored zone. Additional data collected in the ALD confirmed the thickness of the clay is over 120 feet thick and the permeability ranges from  $4.4 \times 10^{-9}$  to  $2.1 \times 10^{-8}$  cm/s.<sup>14</sup> Horizontal groundwater flow potential is consistently to the west-northwest (Application Figures 6-10) with strong vertical upward gradients (Application Section 2.4). The silt aquifer represents a single hydrostratigraphic unit beneath the clay. Due to the strong upward gradients in combination with the laterally contiguous nature of the silt, it is appropriate to place the monitoring wells within the uppermost aquifer saturated silt, beneath the clay, to ensure detection of any potential leakage from the CCR unit. The consistency observed in the groundwater flow direction since monitoring began in 2016 ensures that groundwater is constantly flowing in the direction of the three downgradient monitoring wells installed along the west-northwestern perimeter of the DB and confirms that these monitoring wells are appropriately placed to intercept groundwater flowing beneath the DB.

<sup>13</sup> Application, p. 3-5.

<sup>14</sup> April 2023 DB Final ALD, p. 3-3.

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin

Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

Bottom Ash Basins Aquifer Characteristics:

— As detailed in the Application,<sup>15</sup> the BABs is underlain by more than 130 feet of unconsolidated sediments, with the lower confining Bedford Shale generally encountered from 135 to 145 feet below ground surface (bgs). In general, the BRPP BABs CCR unit is initially underlain by at least 90 to as much as 142 feet of laterally extensive low hydraulic conductivity clay-rich deposits. The depth to the top of the confined sand-rich uppermost aquifer encountered immediately beneath the clay confining unit varies up to 46 feet and rapidly thins to the south and east of the BABs and pinches out (e.g., is not present) to the southeast in the vicinity of SB-16-01. Consequently, the uppermost aquifer is not laterally contiguous across the entire site, nor is it contiguous across BRPP BABs CCR Unit, and not present beneath the southeastern corner of the BABs (Application Figures 3-5) The variability in the depth to the uppermost aquifer is a consequence of the heterogeneity of the glacial deposits and is driven by the lateral discontinuity of the sand outwash within the encapsulating fine-grained, silty clay till that confines the uppermost aquifer. The at least 82 feet thick, contiguous clay soil beneath the BABs serves as a natural confining hydraulic barrier that isolates the underlying aquifer across the entire site (Application Figures 3-5). Additional data collected in the ALD confirmed the thickness of the clay ranges is at least 82 feet thick beneath the BABs and the permeability ranges from  $4.4 \times 10^{-9}$  to  $2.1 \times 10^{-8}$  cm/s<sup>16</sup>.

A definitive groundwater flow direction is not evident around the BABs based on monitoring performed from 2016 through 2022. As such, it is not appropriate to infer horizontal flow direction or gradients across the BRPP BABs CCR unit.

---

<sup>15</sup> Application, p. 3-6.

<sup>16</sup> April 2023 BABs Final ALD, p. 3-3

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

Given the site hydrogeological conditions, additional upgradient wells would provide little value due to the extremely low horizontal flow rates observed in the uppermost aquifer beneath both the BABs and DB that would not represent groundwater that could even reach the area of the monitoring system within the timeframe of the monitoring programs. There is no observed flow direction at the BABs, however, there are upgradient wells established at the DB that further confirm background groundwater conditions at the site. Horizontal travel times demonstrate the impracticality of additional upgradient wells. Since there is no flow direction at BABs, flow rates are estimated using the gradients observed from the DB wells. Conservatively assuming the hydraulic gradient of 0.003 at the BABs with the hydraulic conductivity of the sand-rich uppermost aquifer (~0.5 feet/day) and a conservative low effective porosity of 0.2 for the sand (resulting in higher flow rates calculated) a conservative horizontal travel time of approximately 3 feet per year in the fine sand (BABs uppermost aquifer material) or approximately 0.6 feet per year (from DB 2017 to 2022 Annual Reports) in the silt (DB uppermost aquifer material). Add in a contingency factor of 10x and that is no more than 30 ft per year of potential migration within the BABs uppermost aquifer.

The other key consideration in determining the lateral and vertical placement of the monitoring well network are the physical and chemical characteristics of the potential contaminants of concern. The groundwater monitoring system is used to identify potential releases from the CCR unit by monitoring the Appendix III constituents (boron, calcium, chloride, fluoride, pH, sulfate, and total dissolved solids [TDS]) (§ 257.94). The Appendix III constituents are known leading indicators of releases and were selected as primary indicators in detection monitoring due to, among other qualities, their elevated concentrations (typically) in the CCR material being managed and their generally high mobility and low reactivity in the environment. These properties allow Appendix III constituents to travel readily through groundwater (transport is advection-dominated), remain detectable in the waste and groundwater, and provide early detection of potential leakage from the CCR unit being monitored. Based on these properties, Appendix III parameters can be expected to be fairly ubiquitous (not concentrated at a particular depth) and migrate throughout groundwater at approximately the rate of groundwater flow, therefore

## DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

installation of the compliance wells in the downgradient direction of flow is appropriate. Groundwater is confined with hydraulic head levels well above the top of the uppermost aquifer, demonstrating significant upward flow potential, in addition, the Appendix III constituents are readily going to move with groundwater, therefore, screening at the depth of first saturation in the uppermost aquifer (as was done at the BABs CCR unit albeit at different elevations due the thickness of overlying clay across the unit varying somewhat) is ideal for early detection of groundwater influenced by potential leakage from the BABs.

Based on these two key considerations, the groundwater monitoring system clearly meets the performance standard of § 257.91(a) and accomplishes EPA's stated objective in the Proposed Decision<sup>17</sup> that says "[t]he objective of a groundwater monitoring system is to intercept groundwater to determine whether it has been contaminated by the CCR unit being monitored."

Further, not only has the network been certified by a QPE per the rule and meets the performance standards set forth in § 257.91(a), the monitoring system has been approved by the Michigan Department of Environment, Great Lakes and Energy (EGLE) for groundwater monitoring in compliance with the Natural Resources and Environmental Protection Act, Act 451 of 1994, as amended, Part 115 Solid Waste Management regulations.

### **B. The CCR Impoundments Properly Remain in Detection Monitoring**

DTE's Application successfully 1) documents that the groundwater monitoring systems at the BABs and DB meet all the requirements of 40 C.F.R. §§ 257.93 through 257.94, and 2) demonstrate that the BABs and DB appropriately remain in detection monitoring.

#### **1. Sampling and Analysis Program**

Statistical analysis is a principal component of the CCR rule groundwater monitoring program. As summarized in EPA's Unified Guidance,<sup>18</sup> the fundamental goals of the CCR

---

<sup>17</sup> Proposed Decision, p. 13.

<sup>18</sup> U.S. EPA. 2009. "Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities: Unified Guidance." EPA 530-R-09-007. Office of Resource Conservation and Recovery. Washington, DC. March. p. 1-1.

## DTE Electric Comments

Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

rule groundwater monitoring regulations are fairly straightforward. Regulated parties are to accurately characterize existing groundwater quality at their facility, assess whether a CCR release has occurred and, if so, determine whether measured levels meet the compliance standards. Using accepted statistical testing methods, evaluation of groundwater quality should have a high probability of leading to correct decisions about a facility's regulatory status. Essentially, this is accomplished through the framework provided in the CCR rule under with § 257.93 and § 257.94 that requires groundwater compliance monitoring be statistically compared to background groundwater quality through implementation of the detection monitoring program.

The following section provides additional discussion and clarification of information related to the statistical analysis program performed in accordance with § 257.93 in response to EPA's comments in the Proposed Decision (p. 23-34) that focus on that statistical methods portion of the sampling and analysis program under § 257.93(f) and (g).

### **a. Reliance on Intrawell Comparisons**

There are two general approaches, interwell and intrawell, that are used to perform data comparisons to background as presented in the EPA Unified Guidance and in the EPA Solid Waste Disposal Facility Criteria Technical Manual.<sup>19</sup> DTE considered both of these methods as part of the selection criteria. Interwell comparison methods compare background and compliance data collected from separate spatial locations within the groundwater monitoring system (e.g. upgradient versus downgradient). Whereas intrawell statistical limits compare historical background data (collected from each individual well) to current data from a single location. Both interwell and intrawell comparisons can be useful tools in groundwater monitoring and analysis, however, there are certain conditions that should be considered when selecting which method is appropriate, including site-specific hydrological factors and groundwater data behaviors that may influence the power of the test.<sup>20</sup>

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

As discussed in the Applications, due to the slow horizontal travel velocities (conservatively on the order of 0.6 feet/year at the DB and, assuming some flow is taking place, 3 feet/year at the BABs), the presence of the underlying clay (which results in excessive vertical travel times, that if groundwater were capable of migrating vertically through the clay would take over 1,000 years to reach the uppermost aquifer), the strong upward vertical flow potential of the uppermost aquifer, in addition to the spatial variability observed in the uppermost aquifer dataset, an intrawell statistical program has been selected to perform detection monitoring at all five BABs monitoring wells and all six DB monitoring wells located around the perimeter of each CCR unit to comply with the requirements of 40 C.F.R. § 257.93. This selection is appropriate based on the site-specific hydrogeological considerations and evidence of significant spatial variability across the monitoring well networks attributed to natural conditions in the aquifer (i.e. the uppermost aquifer remains unaffected by CCR operations) that, consistent with the recommendations in the Unified Guidance<sup>21</sup>, warrants the use of intrawell testing because it is a more powerful and appropriate method for detection monitoring under the site conditions that exist at the BABs and DB CCR units. Further discussion below provides additional detail on how the assumptions of interwell are not met and thus support intrawell as a more appropriate and powerful test for the BABs and DB.

*i. Groundwater Velocity*

One of the assumptions in background-to-downgradient comparisons (i.e. interwell comparison) presented in the Unified Guidance, is that “[g]roundwater flow should also move at a sufficient velocity beneath the site, so that the same groundwater observed at upgradient well locations is subsequently monitored at downgradient wells in the course of an evaluation period (e.g., six months or a year). If groundwater flow is much slower, measurements from upgradient and downgradient wells may be more akin to samples from two separate aquifers. Extraneous factors may separately influence the downgradient and

EPA-HQ-OLEM-2021-0282  
April 10, 2023

background populations, confusing the determination of whether or not a release has occurred.”<sup>22</sup>

Specifically at the BABs, there is approximately 545 ft horizontal distance between MW-16-02 and MW-16-04 across the CCR unit roughly south to north and approximately 725 ft horizontal distance from MW-16-01 to MW-16-09 west to east across the CCR unit. Based on multiple rounds of data collection (8 background monitoring events 2016-2017 and 11 semiannual monitoring events 2017-2022), there is no definitive groundwater flow direction at the BABs, therefore, assumptions are made regarding potential flow paths in order to demonstrate the extremely slow nature of groundwater flow beneath the BABs. Conservatively assuming the groundwater horizontal seepage velocity of ~3 feet/year, as presented above, this results in at least 180 years travel time from the upgradient to downgradient edge of the BABs. Even if a hypothetical groundwater velocity on the order of 10x higher than the average were to be assumed, groundwater flow would still be much slower than the 6-month evaluation period (on the order of 30 feet/year with at least 18 years travel time). The groundwater horizontal seepage velocity beneath the DB is even lower (~0.6 feet/year) therefore groundwater flow would be much slower than the 6-month evaluation period than it is for the BABs.

*ii. Definable Flow Path*

For interwell comparisons to be valid, there needs to be a definable flow pathway from upgradient to downgradient wells beneath the regulated unit.<sup>23</sup> There is no identifiable groundwater flow direction at the BABs, therefore, no definable flow path and the assumptions of the upgradient-downgradient comparison method cannot be met.

*iii. Spatial Variability*

The EPA’s Unified Guidance recommends the use of intrawell comparisons in situations where spatial variability is present – this is a reoccurring message

---

<sup>22</sup> Unified Guidance, p. 6-29.

<sup>23</sup> Unified Guidance, p. 6-29.

that is reinforced in multiple chapters throughout the Unified Guidance, including an entire chapter dedicated to spatial variability and ways to identify it (see Chapter 13). Specifically, in reference to spatial variation across the well network, the Unified Guidance states: “If evident, the statistical approach would need to be modified so that distinct wells are treated as individual populations with statistical testing being conducted separately at each one (i.e., intrawell comparisons).”<sup>24</sup> The presence of significant spatial variability can invalidate the interwell method.

From the Unified Guidance Chapter 5,<sup>25</sup> “[i]f the spatial variation is ignored and data are pooled across wells with differing mean levels (and perhaps variances) to run an interwell parametric prediction limit or control chart test, the pooled standard deviation will tend to be substantially larger than expected. This will result in a higher critical limit for the test. Using pooled data with spatial variation will also tend to increase observed maximum values in background, leading to higher and less powerful non-parametric prediction limit tests. In either application, there will be a loss of statistical power for detecting concentration changes at individual compliance wells. Compliance wells with naturally higher mean levels will also be more frequently determined to exceed the limit than expected, while real increases at compliance wells with naturally lower means will go undetected more often.” This further demonstrates that significant spatial variability can reduce the power of the test by introducing higher variability in the background dataset and “exaggerating” the background limit.

EPA states in the Proposed Decision that “the Application does not consider the effect of the smaller background dataset that would result from reliance on downgradient compliance wells. When relying on upgradient wells to establish background concentrations, the data collected from each additional well can be pooled and used to increase the initial baseline sample size.”<sup>26</sup> However, EPA’s

EPA-HQ-OLEM-2021-0282

April 10, 2023

comment does not consider the effect of using an incorrect statistical model for detection monitoring. The goal of detection monitoring is to correctly discern whether a release has occurred from the CCR unit. Having a statistical method with theoretically high power that ignores the hydrogeological facts of the unit will not achieve that goal. As discussed multiple times throughout the Unified Guidance, spatial variability must be a consideration in determining an appropriate statistical test. In the case of the DB, there is significant spatial variability in concentrations within the three upgradient monitoring wells. When pooled, this would result in a similar scenario as described above with the tests having lower statistical power. Although sample size of the background dataset is indeed a consideration, a larger background does lead to more power, there are recognized limitations in sample size during the onset of a detection monitoring program that can be resolved by updating background as described in and advocated for by in the Unified Guidance [see Chapter 5].

Per the EPA's Unified Guidance, "the goal of groundwater analysis is not simply to identify significant concentration differences among monitoring wells at compliance point locations. It is also to determine why those differences exist."<sup>27</sup> Recognizing spatial variability and why it exists and assigning the appropriate statistical approach to account for the spatial variability is even more important than ensuring that normality assumptions are met. In order to apply intrawell analysis, the aquifer must remain unaffected by releases from the CCR unit. The Unified Guidance recognizes that the determination of whether an observed pattern of spatial variation is natural and not synthetic requires expert judgment and knowledge concerning site hydrogeology and geochemistry to provide more definitive answers.<sup>28</sup> As detailed in the Application, DTE has performed that analysis and has determined that the aquifer is unaffected by the operation of the CCR unit using multiple lines of evidence. DTE has further studied the uppermost aquifer and has provided

additional geochemical, stable isotopic, and radiogenic data that further confirm the uppermost aquifer is unaffected by CCR operations at the BABs and DB.

Further analysis of the spatial variability is also provided herein to further demonstrate that the assumptions of interwell are invalidated due to the spatial variability across the well network, and between the two upgradient background wells. Thus, here the use of intrawell methods is more appropriate and provides a more powerful statistical approach. Spatial variability was assessed on the dataset collected from all six monitoring wells at the DB, and all between August 2016 and April 2022 using box plots and analysis of variance (ANOVA) tests as recommended by the Unified Guidance (see Chapter 13). The results of the ANOVA test show significant variance is observed for boron, calcium, chloride, fluoride, sulfate and TDS across the entire well network. This is not unexpected. According to the Unified Guidance, indicator parameters are more likely to exhibit spatial variation.<sup>29</sup>

Box plots provide a visual display of the variability and illustrate the differences in mean concentration observed at each well. Examples for calcium, chloride, and sulfate for the DB are shown below.

EPA-HQ-OLEM-2021-0282

April 10, 2023

As shown in the box plots, some concentrations in the background wells (i.e. calcium at MW-16-07 and MW-16-08) are much higher compared to the downgradient wells. That even when pooled, would result in a significantly higher concentration in the upgradient wells compared to the downgradient wells, lowering the sensitivity of the test and reducing the efficiency in detecting an increase in the downgradient wells.

Data populations were also compared using box plots to assess spatial variability between the three upgradient wells (MW-16-06, MW-16-07, and MW-16-08) for each of the Appendix III constituents. The results show evidence of significant difference between the three data populations, showing differences in mean concentrations and standard deviations within the background wells for boron, calcium, chloride, sulfate and TDS. Box plots for TDS and boron are provided below, illustrating the differences between the background wells. To further compare the upgradient and downgradient data populations t-tests were also between the pooled upgradient wells (MW-16-04 and MW-16-05) and the pooled downgradient wells (MW-16-01, MW-16-06, and MW-16-07). This

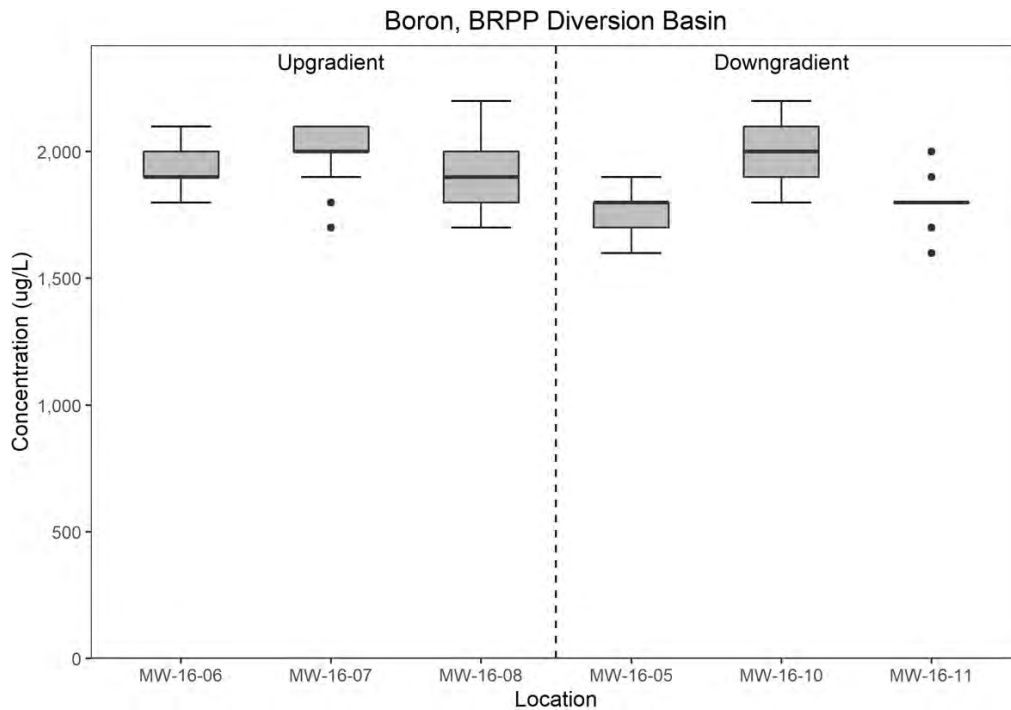

DTE Electric Comments

EPA-HQ-OLEM-2021-0282

April 10, 2023

resulted in significant differences between the upgradient and downgradient populations for boron, calcium, chloride, and TDS. Looking at the concentrations, the upgradient wells have higher concentrations of calcium and chloride, and lower concentrations of boron and sulfate when compared to the downgradient wells.

The dataset exhibits significant spatial variability across the well network for multiple Appendix III constituents that, as demonstrated through the Aquifer Characterization Study and the historical record for the site, is clearly the result of natural groundwater chemistry (not due to influence from the CCR unit). Due to the spatial variability and the aforementioned hydrogeological considerations, including the slow and insufficient groundwater velocity across the site, several key assumptions of interwell tests are not met, therefore, intrawell methods are appropriate at the BABs and DB.

**b. Use of Appropriate Statistical Distributions**

The CCR rule provides a framework for groundwater monitoring and defines the conditions under which statistical testing takes place. Specific statistical methods are identified in the CCR rule, just as they are in the RCRA regulations, but their application is not described in any detail. In order to implement a statistical analysis program, professionals must rely upon mathematical models and calculations, but just as importantly, professional experience and qualified decision making to navigate the complexities of applying statistics to groundwater data.

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

The CCR rule itself accounts for this by requiring OPE certification as the regulatory mechanism for demonstrating compliance with the statistical method under § 257.93(f)(6).

Because a statistical model is at best an approximation of reality, all statistical tests and procedures require certain assumptions for the methods to be used correctly and for the results to be properly interpreted.<sup>30</sup> There are generally two types of statistical tests used in groundwater monitoring programs, parametric and non-parametric tests. Both of these statistical tests rely on the construction of a binary hypothesis test. The power of a binary hypothesis test is the probability that the test correctly rejects the null hypothesis when a specific alternative hypothesis is true. This probability represents the chances of a true positive detection conditioned on the actual existence of an effect. As a result, as the power of a test increases, the probability of wrongly failing to reject the null hypothesis (i.e. false negative) decreases.

Of these two statistical methods, parametric tests offer more statistical power and are preferred over non-parametric tests. However, most parametric test methods make a critical assumption that the underlying data follow a normal distribution, and if that underlying assumption is violated, it can impact the validity or accuracy of the test.<sup>31</sup> For this reason, it is important to check the normality of the dataset prior to selecting the appropriate statistical test. Non-parametric tests do not rely as heavily on the underlying data distribution; however, non-parametric tests require larger sample sizes than the parametric tests to ensure a similar level of statistical power.<sup>32</sup> So as long as the underlying distribution assumptions are met, parametric tests are preferred over non-parametric tests.

A statistical distribution is a mathematical model used to represent the shape and statistical characteristics of an unknown population (e.g., the concentrations of Appendix III constituents in groundwater upgradient of a CCR unit) that forms the

basic building blocks of all statistical testing procedures.<sup>33</sup> A distribution in statistics is a function that shows the possible values for a variable and how often they occur. A normal distribution is typically bell-shaped. There are multiple techniques presented in both the EPA's Unified Guidance and EPA's ProUCL Technical Guide to assess data distributions and determine whether normality is observed in the dataset,<sup>34</sup> thus ensuring that the underlying assumption of normality are appropriately met under 40 C.F.R. § 257.93(g)(1). Despite there being many types of normality tests available, based on the information provided by the Agency, EPA's comments in the Proposed Decision rely solely on one particular normality test and exaggerate the effectiveness of the recommended Type I error rate for that specific normality test, which has no practical effect on compliance at the BABs or DB.

The methods used by DTE to determine the selected distributions were appropriate for the available monitoring data, as required by 40 C.F.R. § 257.93(g)(1) and were developed using the QPE-certified statistical analysis plan developed for the site. 40 C.F.R. § 257.93(g)(1) does not prescribe the exact distribution test to be used to assess normality in the dataset, nor does it expressly state the Type I error rate to be used in normality testing. Data distribution is a function that specifies all possible values for a variable and also quantifies the relative frequency (probability of how often they occur). The EPA's Proposed Decision relies exclusively on the Shapiro-Wilk test for normality, when in fact there are several methods available to determine appropriate distributions, many of which are described in the EPA's Unified Guidance. A combination of several methods is typically used to test the normality of the dataset as described in the Unified Guidance, such as graphical (i.e. visual) methods that explore possible patterns present in data sets and numerical (i.e. quantifiable) methods that are often supplementary to visual methods. DTE used multiple methods to test normality, including skewness tests,

probability plots, and Shapiro-Wilk tests to verify the distribution of the data as shown in Applications Appendix E and I.

EPA's selective references to the Unified Guidance are misleading. Using the multiple methods recommended by the EPA's Unified Guidance and allowable by § 257.93(g)(1) to test the distribution of the dataset does not necessarily include an associated Type I error rate. However, as stated above, § 257.93(g)(1) does not prescribe which distribution test must be used, nor does it require a correspondent Type I error rate, to assess normality in compliance with the CCR rule. Section 10.3 of the Unified Guidance states that "Assumptions of normality are most easily made with regard to naturally occurring and measurable inorganic parameters, especially under background conditions." These are the conditions applicable to Appendix III parameters. The EPA's ProUCL Version 5.0.00 Technical Guide notes that "goodness-of-fit (GOF) tests to determine data distribution (such as the Shapiro-Wilk test for normality) often fail if there are not enough observations (e.g., <20 observations), or if the data contain multiple populations, or if there is a high proportion of non-detects in the collected data set. Tests for normality lack statistical power for small sample sizes. In this context, a sample consisting of less than 20 observations may be considered a small sample. However, in practice, many times it may not be possible (due to resource constraints) to collect data sets of sizes greater than 10." This further supports that ***reliance solely on the formal Shapiro-Wilk test is not appropriate to verify normality, particularly at the onset of a new monitoring program*** where datasets are typically limited to less than 10 observations.

EPA's comments in the Proposed Decision contradict the recommendations in EPA's Unified Guidance and the EPA's ProUCL Technical Guide by over emphasizing ways to identify non-normal distributions, rather than performing a more thorough assessment that the data population is normally distributed (i.e., the null hypothesis is met). Particularly when taking into consideration the pitfalls of using only a goodness-of-fit test and incorrectly assigning non-normality using the limited background dataset available for Appendix III constituents at the onset of the monitoring program. The Unified Guidance, page 18-6, states that "When

DTE Electric Comments

Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

normality cannot be justified, a non-parametric prediction limit should be considered instead. A non-parametric limit assumes only that all the data come from the same, unusually unknown, continuous population. Non-parametric prediction limits generally require a much larger number of background observations in order to provide the same level of confidence as a comparable parametric limit. Consequently, the Unified Guidance recommends that a parametric model be fit to the data **if at all possible** [emphasis added]."

The Unified Guidance contemplates exploration of different distribution models (i.e. mathematical transformations of the raw measurements) to exhaust all options to identify normality in the underlying dataset before assigning a non-normal distribution. The original values can be transformed into a set of numbers that behaves as if drawn from a normal distribution. The transformed values can then be utilized in and analyzed with a normal-theory test (i.e., a procedure that assumes the input data are normal).<sup>35</sup> This is clearly laid out in the Unified Guidance example of fitting distributions using a Shapiro-Wilk test.<sup>36</sup> The Shapiro-Wilk test can be used to test normality for datasets with fewer than 50 observations ( $n \leq 50$ ). A significance level is selected to establish the critical point to compare against when running the statistical test for normality (i.e. assess whether the resulting test statistic is above or below the critical point based on the assigned significance level). The Unified Guidance generally recommends selecting a significance level of 0.01 for very small datasets ( $n < 10$ ), 0.05 for moderately sized datasets ( $10 \leq n < 20$ ), and 0.01 for larger data sets ( $n \geq 20$ ).<sup>37</sup> When the Shapiro-Wilk statistic exceeds the critical point, normality can be accepted as a reasonable model for the underlying population. However, if the Shapiro-Wilk test rejects normality at that significance level, additional testing is recommended by the Unified Guidance to see if another distribution model provides a better fit.<sup>38</sup> If the Shapiro-Wilk test shows significant evidence of nonnormality (i.e. does not meet the critical point), then "the data should be transformed using logarithms or

EPA-HQ-OLEM-2021-0282

April 10, 2023

another transformation on the ladder of powers and re-checked using the Shapiro-Wilk test before proceeding with further statistical analysis.”<sup>39</sup> Although it is recognized that in some cases a non-parametric limit is appropriate, as demonstrated in the Unified Guidance, it is a last resort due to its lack of power compared to parametric tests.

DTE’s statistical analysis plans developed for the BABs and DB groundwater monitoring programs also contemplate these transformations in addition to procedures on treating non-detects and potential outliers in the dataset that, if present, can also have a profound effect on normality if not accounted for appropriately. There are several variables necessary to account for in verifying which data distribution assumptions are appropriate for the statistical tests to meet the performance standards outlined in §257.93(g).

It is well understood that statistical power is limited by the sample size and that sample size is limited at the onset of any new monitoring program. This concept is also supported by the EPA’s Unified Guidance that states, “very small individual well samples in the early stages of a monitoring program may make it difficult to utilize an intrawell method having both sufficient statistical power and meeting false positive design criteria.”<sup>40</sup> This is correctable with the addition of new sample data which is incorporated into the background dataset periodically to improve statistical power of the test over time, which is exactly what DTE has done. The statistical power of the tests was improved by updating the background prediction limits once additional observations were available, in accordance with the recommendations in the Unified Guidance (see Chapter 5). This was completed for the BABs and DB units in December 2021 and presented in the respective 2021 Annual Groundwater Monitoring Reports (available on DTE’s CCR rule compliance data and information website<sup>41</sup>), subsequent to submittal of the Application. The number of samples comprising the background set for each well/constituent pair

---

<sup>39</sup> Unified Guidance, p. 10-14.

<sup>40</sup> Unified Guidance, p. 6-34.

<sup>41</sup> <https://www.dteenergy.com/us/en/residential/community-and-news/environment/coal-combustion-residual-rule-compliance-data-and-information.html>

increased from 8 to 16, except for two at the DB that had 15 results after removal of outliers, and one at the BABs with 15 after removal of outliers. Comparing the updated UPLs to the initial ones, 5 well/ constituent pairs moved from nonparametric to parametric, while 3 moved from parametric to nonparametric for the DB, and 1 well/ constituent pairs moved from nonparametric to parametric, while 6 moved from parametric to nonparametric for the BABs. While some of the updated prediction limit values changed, the magnitude of the changes were small.

**c. Effectiveness of Prediction Intervals**

40 C.F.R. § 257.93(f) allows for the use of multiple statistical methods and defers to the QPE to ensure that the selected method meets the minimum performance standards of 40 C.F.R. § 257.93(g) to ensure contamination can be detected. Prediction intervals are calculated based on background samples and are thus frequently used for detection monitoring programs, which is based on comparisons to background water quality. Per the Unified Guidance, prediction intervals provide well established testing strategies for simultaneously controlling false positive rates while maintaining adequate power to detect contamination during detection monitoring, they offer flexibility to accommodate a wide variety of groundwater monitoring networks, and are generally easy to construct and straightforward to interpret.<sup>42</sup> Although the rule itself does not require a minimum nominal false positive rate as specified in 40 C.F.R. § 257.93(g)(2), prediction intervals combined with a retesting strategy can result in sufficiently low Type I error rates and the ability to detect real contamination. From a practical standpoint, prediction limits were selected for the BABs and DB and have been demonstrated to adequately meet the performance standards in 40 C.F.R. § 257.93(g)(4) as discussed below.

Supporting analyses of the 2017 statistical calculations for the BABs and DB programs were provided to the Agency in the Application Appendix E (2017 Annual Groundwater Monitoring Report), which includes details on the statistical limit calculations at the onset of the monitoring program. Chemstat v6.2 statistical software is used to perform the statistical analysis; the associated output files that

EPA-HQ-OLEM-2021-0282

April 10, 2023

show the detail of the background datasets, results of distribution tests, outlier testing, and statistical calculation methods are all included as attachments in the 2017 Annual Groundwater Monitoring Report. DTE also provided the Groundwater Statistical Evaluation Plan for each of the BABs and DB units that provides an overview of the methods and steps that were used to guide these calculations (Application Appendix I). Since 2017, statistical updates have been performed in December 2021 and reported in the respective 2021 Annual Groundwater Monitoring Reports (available to the Agency on DTE's CCR rule compliance data and information website<sup>43</sup> since early 2022). Additional detail is provided below to provide additional clarity and further justify the Type I error rate associated with the prediction intervals used at the BABs and DB and demonstrate the effectiveness of the selected approaches per 40 C.F.R. § 257.93(g)(4).

As discussed in Unified Guidance Chapters 18 and 19, the use of prediction limits requires management of the potential for high site-wide false positive rates (SWFPR), which can become very high in detection monitoring under the CCR rule with seven Appendix III parameters and at least three downgradient monitoring wells. The solution to managing the SWFPR (and the solution to §257.93(g)(4)) is to use a retesting strategy to control the SWFPR. This retesting procedure was contemplated from the onset of DTE's monitoring program as outlined in the BABs and DB Groundwater Statistical Evaluation Plans (Applications Appendix I) and implemented as described throughout the annual groundwater reports since 2017 (Applications Appendix C, D, and E, and CCR rule compliance data and information website<sup>44</sup>). For parametric prediction limits, k-multipliers are continuous statistical parameters that can be adjusted to match a desired false positive rate. As discussed by EPA in the Proposed Decision,<sup>45</sup> the Unified Guidance provides a set of tables that enable the estimation of the power provided by prediction limits with various resampling strategies. The series of tables were established with

<sup>44</sup> <https://www.dteenergy.com/us/en/residential/community-and-news/environment/coal-combustion-residual-rule-compliance-data-and-information.html>

<sup>45</sup> Proposed Decision, p. 31-32.

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

calculated k-multiplier values to meet a SWFPR of 10 percent, which exceeds the minimum of 5 percent established in §257.93(g)(2), under various testing scenarios (interwell or intrawell) with a given sample size and number of tests being run. Using the tables in Unified Guidance Appendix D.3 for intrawell prediction limits with a 1 of 2 resampling strategy, and semi-annual sampling with five wells (BABs) and six wells (DB) with seven constituents (interpolation between tables required), the initial prediction limits established with 8 sampling results fell marginally below the level having sufficient power compared to the EPA Reference Power Curve (ERPC) at 4 standard deviations (interpolated k-multiplier values of 2.74 for BABs and 2.83 for DB). A similar analysis using the 2021 updated prediction limits (16 observations) fell well within the region of the table exceeding the ERPC levels (interpolated values of 2.10 for BABs and 2.21 for DB). Further, back-calculation of the k-multiplier from the ChemStat data files results in an even lower value. For example, using the dataset specific to TDS in MW-16-07 for BAB and pH in MW-16-02 for DB, the actual k-multiplier values are 2.0 for the initial 8 sampling events and 1.8 for the updated dataset using 16 samples. These lower k-multiplier values are well within the range of values that meet the ERPC, and demonstrate that the aforementioned interpolations are conservative estimates and that the real power for these data sets are actually better than the interpolated general k-multiplier values indicate. Thus, further demonstrating adequate statistical power is achieved to ensure adequate detection of potential contamination and shows that the prediction intervals are in compliance with §257.93(g)(4).

As discussed above, lower statistical power at the onset of monitoring is expected due to the relatively small sample size and is recognized by the Unified Guidance as a challenge at the early stages of the monitoring program. The initial prediction intervals were established with the minimum eight sampling results because, at the onset of the 2015 CCR Rule, hydrogeological characterization and monitoring networks needed to be established, with at least eight baseline samples from each well, within the first two years of implementing the 2015 CCR Rule. This tight timeline to implement the program (including initial site characterization, establishment of monitoring networks prior to even beginning to collect baseline

## DTE Electric Comments

Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

samples) inherently limited the number of baseline datapoints that could be collected and remain temporally independent. DTE has performed the recommended steps set forth in the Unified Guidance to make these improvements as soon as an appropriate number of additional observations were available. DTE completed the updates in 2021 as documented in the 2021 Annual Groundwater Monitoring Reports (available on DTE's CCR rule compliance data and information CCR website<sup>46</sup>).

### *i. Outlier Testing*

Outliers are data points in a dataset that are significantly different from other data points in the same dataset. In other words, they are values that are much higher or much lower than the rest of the data points in the dataset. Outliers can occur for a variety of reasons, such as errors in data collection, measurement errors, or unusual circumstances that are not representative of the normal behavior of the dataset. Outliers can have a significant impact on the analysis of the dataset because they can skew the results or make it difficult to draw accurate conclusions. Therefore, it is important to identify and deal with outliers appropriately when analyzing a dataset. Typically, outliers are removed from a dataset that occurred due to errors or unusual circumstances that are unlikely to occur again. However, in some cases, outliers may be valid data points that represent important information, and in these cases, they should be retained in the analysis. Identification of outliers is key component of statistical testing to ensure that data are representative of groundwater conditions since the presence of even one extreme outlier may cause an otherwise recognizable distribution from being correctly identified.<sup>47</sup>

For the BABs and DB programs, outliers were tested as described in the BABs and DB Groundwater Statistical Evaluation Plans (Application Appendix I) (which align with the recommendations set forth in the Unified Guidance) and

details for specific handling of outliers are included in the documentation of the actual statistical limit calculations provided in Application Appendix E. As stated in the Groundwater Statistical Evaluation Plan (and per the Unified Guidance), data were reviewed graphically using tools such as time concentration trend plots, box and whisker plots and/or probability plots to illustrate and identify outliers, trends, or otherwise unusual observations at each monitoring location. This is accomplished prior to further in-depth review of the data sets to identify any obvious field or laboratory anomalies. Data points that are determined to be nonrepresentative will be 'flagged' for further detailed evaluation prior to removing from the background data or designating as an outlier. Further in-depth review would be a formal outlier test such as Dixon's Outlier Test. Like many steps throughout the monitoring program, there is need for professional judgement in the decision-making process to determine which outliers should be removed. The 2017 Annual Groundwater Monitoring Reports (Application Appendix E) each include a detailed Background Statistical Evaluation technical memorandum that provides a comprehensive, detailed narrative with backup calculations of how the prediction limits were developed. These memorandums provide detail that specifically explains the handling of outliers and demonstrates the step-wise approach and decision making process used to assess suspected outliers through time-concentration graphs, probability plots, and formal outlier testing with Dixon's test, and clearly demonstrates that DTE is taking appropriate steps to develop effective prediction limits that meet the performance standard of 40 C.F.R. § 257.93(g)(4).

In the Proposed Decision, EPA goes against its own guidance by using a statistical test to solely identify and remove outliers from the dataset. In the Unified Guidance, EPA clearly states "The Unified Guidance does not recommend that outliers be removed *solely* on a statistical basis."<sup>48</sup> Per the Unified Guidance, a statistical determination of one or more statistical outliers does not indicate *why* the measurements are discrepant from the rest of the data set. The outlier tests can provide supportive information, but generally a

<sup>48</sup> Unified Guidance, p. 12-1.

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications EPA-HQ-OLEM-2021-0282 April 10, 2023

reasonable rationale needs to be identified for removal of suspect outlier values (usually limited to background data). As such, EPA's rationale for outlier removal in the Proposed Decision is flawed and provides several examples of how EPA is selectively identifying procedural inconsistencies using methods that conflict with their own guidance and the data provided to them in the Application, then they misrepresent their findings (many of which are in error) out of context from the bigger picture and in disregard from the full set of data they were provided. In addition to not following the correct methods and overstating the significance of several of their identified outliers, EPA's comments are fraught with error as detailed below.

In the Proposed Decision, EPA states, "Applying Dixon's test with ProUCL v5.1, EPA identified outliers in the reported intrawell background datasets with 99% confidence at MW-16-04 for total dissolved solids (1,100 mg/L), MW-16-05 for chloride (1,600 mg/L) and pH (9.1), MW-16-07 for total dissolved solids 3,440 mg/L), MW-16-09 for chloride (1,100 mg/L), and MW-16-10 for calcium (170 mg/L). Additional outliers were identified with 95% confidence at MW-16-02 for total dissolved solids (118 mg/L), MW-16-06 for calcium (45 mg/L), and MW-16-07 for calcium (110 mg/L)."<sup>49</sup> There are several missteps and errors in this statement as follows:

- o First, as discussed above, EPA is going against their own guidance by identifying outlier removal solely on a statistical basis. Formal testing for outliers should be done only if an observation seems particularly high or low compared to the rest of the dataset.<sup>50</sup>
- o Second, EPA applies various confidence levels, using both 99% and 95% to justify removal of outliers. The Unified Guidance cautions that removal of outliers should only take place under certain conditions, since a true elevated value may fit the pattern of a release or a change in historical background conditions.<sup>51</sup> By decreasing the confidence level to 95%, the

Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

chances of identifying a statistical outlier are also more likely. This is an example of how strictly sticking to a formal outlier test can end up eliminating data points that are only marginally greater than the bulk of the data.

- o Third, EPA has identified outliers that were in fact already identified and removed as outliers by DTE prior to calculating prediction limits as shown in the Application. This raises concerns with the adequacy of EPA's review and suggests that all of the information presented in the Application was not taken into consideration in the Proposed Decision. The MW-16-10 calcium concentration of 170 mg/L – measured June 2017 was removed as an outlier and the justification for doing so is documented in several places – see DB Application Appendix E, Background Statistical Evaluation Table 1, p. 343. As shown in the table, several outliers were removed from this dataset. The logic and methods for testing and removing these data points are clearly laid out in a series of tables, time-series plots and probability plots with annotations, along with a narrative in the memo that documents the details of the statistical limit calculations performed in 2017,<sup>52</sup> all of which are included in the Application.
- o Fourth, EPA did not consider all of the data provided in the Application. Upon review of EPA's Proposed Decision outlier comments, DTE determined that the noted pH of 9.1 SU from MW-16-05 from September 2017 was a typo in the report table (DB Application Appendix E, Table 2, p. 316). Field records, however, verify that the pH reading from September 13, 2017 is 7.9 SU and the detailed Chemstat output with the dataset used in the prediction limit calculation documents that the correct pH reading of 7.9 SU was used to calculate the prediction intervals (DB Application, p. 397). The Chemstat output also shows that the pH dataset for MW-16-05 was non-parametric, therefore, the highest datapoint of 8.47 SU was used to calculate the upper prediction limit (the resulting PL is 8.5 SU using the correct number of significant digits), not the value of 9.1. This also

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin

#### Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

demonstrates that DTE is performing these statistical calculations based on appropriate methods and is not trying to inflate or misrepresent the prediction limits by disingenuously keeping “extreme” datapoints in the dataset.

- o Fifth, EPA is selectively focusing on high data points as outliers and ignoring the low ones. This is evidenced by the fact that all of the outliers pointed out by EPA that can be confirmed in DTE’s dataset represent maximum concentrations observed during background data collection (August 2016 through September 2017). For example, the MW-16-10 calcium concentration (170 mg/L) was a high datapoint that was removed as an outlier, there were also several extreme low data points (e.g. boron and chloride) at MW-16-10 that were identified by DTE as outliers and removed from the background dataset prior to calculating the predictions limits. It is important to assess both high and low outliers to ensure appropriate distribution assumptions are met and ensure data are representative of groundwater conditions and not due to a potential error in the data. Both high and low extreme datapoints can incorporate variability in the dataset that can impact the power of the test.
- o Sixth, several of the data points EPA listed as outliers that do not exist in DTE’s dataset:
  - MW-16-02, TDS 118 mg/L – lowest TDS at this well is 710 mg/L using data collected from August 2016 through October 2022
  - MW-16-07, TDS 3,440 mg/L – this does not match our dataset, 3,400 mg/L measured January 2017 is the historic max

These data points do not exist in the dataset for these wells. The detailed backup of the datasets used to calculate the 2017 prediction limits are in Appendix E of each of the Applications. EPA did not provide any detail to support their analyses nor did they specify which dataset was used to evaluate outliers, therefore, DTE cannot fully evaluate these discrepancies, however, DTE can conclude that the dataset EPA used to make this determination is incorrect.

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin

### Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

- Seventh, the EPA identified several maximum concentrations that do not constitute outliers, as follows:
  - MW-16-04, TDS 1,100 mg/L – measured January 2017 (reoccurrence in April 2021)
  - MW-16-05, chloride 1,600 mg/L – measured June 2017 (reoccurrence in October 2022)
  - MW-16-09, chloride 1,100 mg/L – measured November 2016
  - MW-16-06, calcium 45 mg/L – measured August 2016 (reoccurrence in April 2022)
  - MW-16-07, calcium 110 mg/L – measured August 2016

As established above, it is not recommended by the Unified Guidance to remove outliers solely based on statistical outlier testing. Again, several factors are used to appropriately identify outliers, starting with visual inspection of the dataset using tools such as time-series plots to first identify any extreme datapoints (both high and low), followed by additional tests such as probability plots and formal outlier tests. The maximum concentration in a dataset is not automatically designated as an outlier simply because it is higher than the other background data.

Groundwater concentrations often fluctuate over time due to seasonal or temporal changes and it is important to capture this variability in the dataset if it represents actual groundwater conditions. In order to be considered an outlier, the datapoint must be significantly high or low compared to the rest of the dataset. As shown on Appendix A Table 2 of each of the 2017 Annual Groundwater Monitoring Reports (DB Application p.316-321, BAB Application p. 328-332) and the Appendix C time-series plots (DB Application p. 347-353, BAB Application p. 347-354), these datapoints flagged by EPA are not “extreme” in comparison with the other data points, therefore, formal outlier testing is not warranted. The time-series plots also illustrate how concentrations in groundwater can vary at specific points in time consistently across the well network and show that these slightly higher occurrences are not

## DTE Electric Comments

EPA-HQ-OLEM-2021-0282

April 10, 2023

isolated. Other factors are also used to evaluate potential outliers before justifying their removal, such as data quality review and reoccurrence of the concentrations in relation to other datapoints, including looking at sample duplicates and confirmatory results, if available. Based on the limited information provided in the Agency's analysis, EPA's selection of outliers does not take any of these considerations into account.

- Lastly, EPA is overstating the significance that these false outliers would make on the resulting prediction limits if removed (listed in the aforementioned seventh bullet point). Take the MW-16-04 TDS concentration of 1,100 mg/L for example. The sample mean of the background dataset with this data point included is 984 mg/L with a non-normal distribution (non-parametric limit is calculated). Removal of the datapoint results in a sample mean of 970 mg/L and would be normally distributed (parametric limit is calculated). The upper prediction limit with the maximum concentration removed would result in a marginal difference, changing from 1,100 mg/L to 1,000 mg/L. However, per the methods in the Unified Guidance, the data point should not be considered an outlier because it meets data quality objectives, and it is not "extreme".

Further, additional groundwater background data collected through April 2021 was presented in the 2021 Annual Groundwater Monitoring Report (available to the Agency on DTE's CCR rule compliance data and information website<sup>53</sup>) and data were reassessed for outliers as part of the 2021 prediction limit update process. With more samples, there are more data available to assess patterns and assess potential outliers. Similarly to what was done in 2017, a detailed technical memorandum is provided as Attachment C to each of the annual reports that details the methods and procedures used to update the prediction limits in 2021. Several potential outliers (high and low) were flagged and subsequently removed as noted in detail in the reports. None of the outliers that EPA flagged in the Proposed Decision were identified as outliers in DTE's

2021 analysis, further confirming that the EPA's comments are in error. However, two outliers for calcium were identified using the aforementioned screening process during the 2021 prediction limit update, which provides an example of how outliers are treated and documented throughout the program. The data presented in Appendix C of the 2021 Annual Groundwater Monitoring Report demonstrates the step-wise approach and decision making process used to assess suspected outliers through time-concentration graphs, probability plots, and formal outlier testing with Dixon's test, and further demonstrates that DTE is taking appropriate steps to develop effective prediction limits, based on sound professional judgement and qualified experience, that meet the performance standard of 40 C.F.R. § 257.93(g)(4).

**d. Alternate Source Demonstration is Adequate**

As presented in the Application, the facility appropriately remains in detection monitoring in accordance with § 257.94 of the CCR rule. The BABs PALD, ALD and the Aquifer Characterization Study provide additional detailed site information that further substantiates the conceptual site model at the site and the BAB ASD, and further verifies that the BABs have not impacted groundwater.

Aside from being performed under direction of a QPE and having obtained the certification required by the rule, the ASD includes multiple lines of evidence that demonstrate the source is from something other than the CCR unit. Per the EPA's Unified Guidance, "the goal of groundwater analysis is not simply to identify significant concentration differences among monitoring wells at compliance point locations. It is also to determine why those differences exist."<sup>54</sup> Under RCRA (§258.54) and the CCR Rule (§257.94), the owner or operator may demonstrate that a source other than the [CCR unit] caused the statistically significant increase (SSI) over background levels for a constituent or that the SSI resulted from error in sampling, analysis, statistical evaluation, or natural variation in groundwater quality. These are often referred to as "alternate source demonstrations" or ASDs. These demonstrations have been an important consideration in solid waste

EPA-HQ-OLEM-2021-0282  
April 10, 2023

groundwater monitoring programs since RCRA was enacted decades ago in order to identify SSIs due to factors unrelated to the unit being monitored. This is especially relevant given that all of the constituents being monitored under the CCR Rule are naturally present in the environment, and in particular, the Appendix III constituents, are very commonly present at detectable concentrations in groundwater.

Fundamentally, groundwater chemistry is influenced by the interaction of aquifer materials in various minerals, gases, and groundwater constituents that are available to react with the water as it travels through the subsurface. Therefore, groundwater naturally has dissolved-phase constituents which can dissolve from the aquifer material (increasing their concentration in groundwater) or precipitate onto the aquifer material (decreasing their concentration in groundwater). Their mere presence in groundwater does not indicate that a release has occurred, nor does an increase in concentration necessarily indicate a release. There are many variables that contribute to natural differences that occur in groundwater quality. Oftentimes increases observed in detection monitoring are caused by natural changes in groundwater quality related to geo-environmental variations that occur throughout the aquifer and are attributable to geogenic sources. These changes can also occur seasonally due to natural processes and regional groundwater fluctuations such as flow rates, geochemistry, and water levels. As such, additional evaluation into the cause of an initial SSI is appropriate to be sure that the change is attributable the CCR unit.

DTE prepared an ASD in August 2019 for an initial SSI for sulfate at MW-16-04 (27 mg/L) and TDS at MW-16-01 (960 mg/L), marginally above their respective prediction limits (PLs) of 18 mg/L (sulfate) and 950 mg/L (TDS). The ASD was included in the 2019 Annual Groundwater Monitoring Report and submitted to the EPA within the Application (Appendix C). The ASD concluded that the two SSIs were attributable to natural variability, largely relying on the isolated occurrence and small magnitude of each increase, the lack of hydraulic connection between the CCR unit and the uppermost aquifer, and the relatively short timeframe at the

EPA-HQ-OLEM-2021-0282

April 10, 2023

start of the monitoring program that did not account for long-term temporal changes (i.e. small background dataset available to calculate the prediction limits).

EPA is proposing to find the information provided in the Application is insufficient to conclude that local subsurface geology would have prevented leakage from reaching groundwater within the operational life of the impoundment based on the theoretical groundwater flow rates used in the evaluation in addition to alleged inadequate data to demonstrate the continuity and consistency of the low permeability of the underlying clay, along with the irrelevance of the background timeline.<sup>55</sup> The significant amount of data provided to EPA in the Application and the multiple site characterization studies demonstrate that the impervious clay-rich soil beneath the BABs is laterally continuous, substantially thick, and hydraulically separates the CCR unit from the uppermost aquifer. These details are further enumerated below in Section VIII.D of this letter and further support the conclusions of the ASD.

The flow rate calculations used to assess groundwater flow rates are appropriate and are recommended by EPA's RCRA draft Technical Guidance (1992) and EPA's Solid Waste Technical Guidance (1993) and are in-line with industry standards and the principles of hydrogeology. The average linear velocity of groundwater flow is derived from Darcy's Law and is a function of hydraulic conductivity, hydraulic gradient, and effective porosity. As detailed in the CCR Rule, "Darcy's Law for gravity flow through porous media is directly proportional to the hydraulic gradient. The use of Darcy's Law to calculate fluid flow through porous media is a well-established and generally accepted engineering methodology."<sup>56</sup> The 1976 Bechtel Subsurface Investigation and Foundation Report, Belle River Units 1&2, (included as Appendix K in the Application) provided data that demonstrated that the clay-rich soil in the area of the BABs has a maximum hydraulic conductivity of  $3.0 \times 10^{-8}$  cm/s and the 2016 clay-rich soil in samples collected by TRC (included in Appendix A of the Application) had a hydraulic conductivity ranging from  $2.1 \times 10^{-8}$  to  $2.9 \times 10^{-8}$  cm/s. While groundwater has the ability to move horizontally through higher

EPA-HQ-OLEM-2021-0282

April 10, 2023

permeability zones, it also has to pass vertically through the most restrictive low permeability material first. As discussed in more detail below, these higher permeable zones are not continuous.

The flow calculations presented in the ASD estimate that, due to the consistently low permeability of the clay and the considerable thickness of the clay, it would take over 1,300 years to travel through the clay, which is well over the less than 40 years of operation of the BABs CCR unit. The addition of more data collected in the ALD confirms the continuity of the clay, and further refines the thickness of the clay to 82 feet beneath the bottom of the BABs, with a hydraulic conductivity of no more than  $2.1 \times 10^{-8}$  cm/s, resulting in vertical travel times of well over 1,000 years (calculated to be approximately 1,300 years), which again is well over 40 years even if a much higher hydraulic conductivity was assumed.

EPA is also proposing “to find that the absence of additional SSIs identified within the same or other monitoring wells is insufficient evidence to conclude that a potential release has not occurred.”<sup>57</sup> DTE acknowledges that the absence of additional SSIs identified within the same or other monitoring wells *on its own* is not a sufficient line of evidence to conclude that a potential release has not occurred in the BABs CCR unit. However, it is a line of evidence to consider in conjunction with other lines of evidence that a release has not occurred. In addition, boron (well known as a very conservative constituent that can move at the rate of groundwater) would be expected to be the first constituent to be seen with a potential SSI in the monitoring well system and a potential boron SSI has not been identified to date.

EPA speculates for the BABs CCR unit that “observed differences among site wells may result from the wells being screened at markedly different depths.”<sup>58</sup> The wells within the BABs CCR unit are all screened within the top of the uppermost aquifer. As discussed above in Section VIII.A.2, groundwater is confined with hydraulic head levels well above the top of the uppermost aquifer, demonstrating

EPA-HQ-OLEM-2021-0282

April 10, 2023

significant upward flow potential. In addition, the Appendix III constituents are readily going to move with groundwater, therefore, screening at the depth of first saturation in the uppermost aquifer as was done at the BABs CCR unit albeit at different elevations due to the thickness of overlying clay across the unit. This is also ideal for early detection of groundwater influenced by potential leakage from the BABs.

Moreover, the timeframe over which the background dataset was collected is sufficient evidence, and highly relevant, to conclude that a potential release has not occurred given the timeframes allowed in the CCR rule. The original proposed CCR rule allowed one year, extended to two years, to perform site characterization, complete the monitoring system design, collect background samples, and develop a statistical analysis program. We agree with EPA that even two years is a very limited and ambitious timeframe to perform the necessary activities, especially for sites with deep wells and difficult drilling conditions. Discussed in the 2015 CCR Rule: "After review of the comments received on this issue and careful reexamination of the actual requirements in the final rule, EPA agrees that a one-year timeframe is not feasible, and has decided to extend the timeframes for completing installation of the system, including background monitoring, to two years."<sup>59</sup> Therefore, as required by the CCR rule, DTE performed the necessary activities to comply with the rule and began detection monitoring at the BABs CCR unit within a two-year period.

As discussed above in detail in Section VIII.B.1.c, the predictive power of the statistics is typically limited due to the relatively small background datasets available at the beginning stages of a monitoring program. The baseline dataset used to develop the initial prediction limits in 2017 were limited by the tight timeframe in which these programs had to be established and limited the number of independent samples that could be collected prior to initiating the detection monitoring program. It is well recognized that statistical power is limited by the sample size and that sample size is limited at the onset of any new monitoring

---

<sup>59</sup> Preamble at 21398.

DTE Electric Comments

Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

program. The initial PLs were the statistical limits available at the time of the TDS and sulfate SSIs. As detailed above, the statistical power is able to be improved over time as more samples are collected. Additional monitoring since 2017 has resulted in additional background data being collected and utilized to update the PLs in 2021 that account for these slight temporal variations in the dataset and improve the statistical power of the test.

Additionally, the sulfate concentrations observed at MW-16-01 and MW-16-04 are not attributable to the BABs CCR unit. The BABs Aquifer Characterization Study (Attachment C of this letter) includes a characterization of the uppermost aquifer water and the CCR contact water, that when compared, further demonstrate that the CCR unit water is not in hydraulic communication with the uppermost aquifer. There are stark contrasts in the geochemical condition of each of the two water groups (CCR contact water and the uppermost aquifer groundwater). For example, sulfate is 15 times more concentrated in the CCR unit water than the concentration in the uppermost aquifer groundwater. When two water masses become hydraulically connected, they tend to become more like each other chemically and physically. The Aquifer Characterization Study shows that the presence of sulfate in the uppermost aquifer is geogenic (i.e. originating from natural geochemical processes within the uppermost aquifer) based on a combination of lines of evidence including geochemistry, stable isotopes, age dating, and statistical analysis which demonstrate the CCR contact water is not mixing with the uppermost aquifer. Moreover, the mineral saturation analysis of groundwater in the uppermost aquifer concludes that "sulfate is expected to dissolve out of the uppermost aquifer material into the groundwater due to the substantial combined undersaturation of sulfate minerals."<sup>60</sup> Therefore, it is not unexpected that sulfate is present in groundwater in the BABs monitoring wells.

Further, the mean sulfate concentrations in groundwater at the BABs monitoring wells are lower than the mean concentrations observed in the upgradient DB

---

<sup>60</sup> BABs Aquifer Characterization, Section 3.1.2.

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

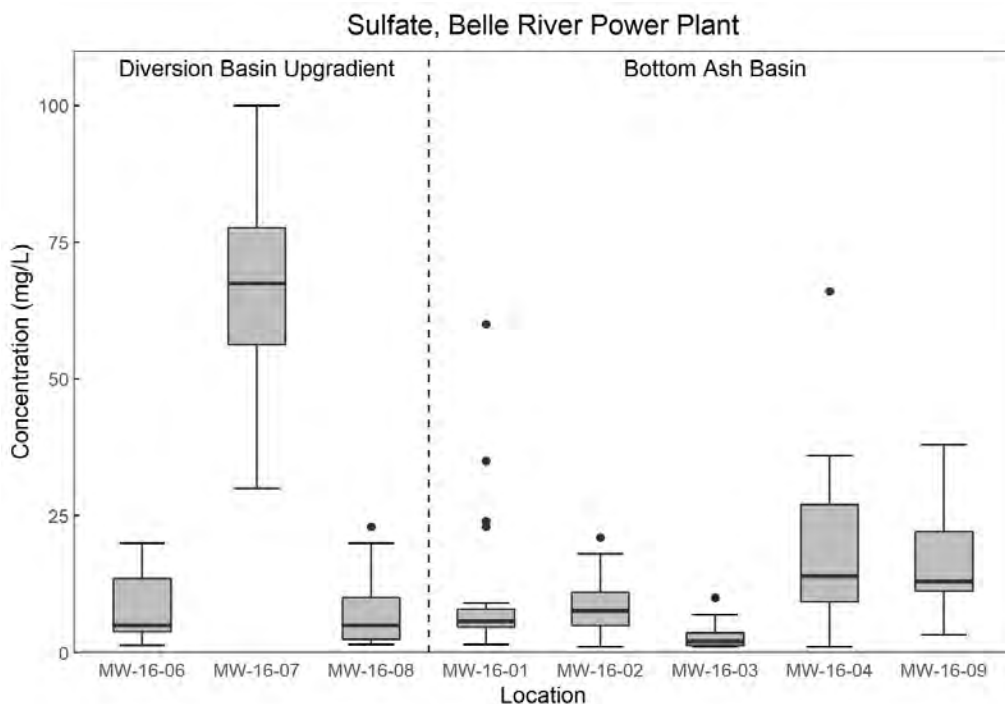

monitoring wells (i.e., MW-16-06, MW-16-07, and MW16-08) as shown in the table below.

Leftside Group	Mean Concentration		Mean C concentration	Rightside Group
DB Upgradient	27.87656	>	10.9	MW-16-01
DB Upgradient	27.87656	O	19.11905	MW-16-04
DB Upgradient	27.87656	>	11.64953	Bottom Ash Basin
MW-16-07	65.93182	>	10.9	MW-16-01
MW-16-07	65.93182	>	19.11905	MW-16-04

- O t-test does not indicate a statistically significant difference between groups
- < t-test indicates concentrations in the leftside group are significantly lower than the rightside group
- > t-test indicates concentrations in the leftside group are significantly higher than the rightside group

t-tests run using Welch's t-test methods at 98% two-tailed confidence

In addition, the BABs sulfate concentrations are well below the highest background concentrations observed in the DB upgradient wells, as shown in the box plot below. This provides further evidence that substantiates the natural occurrence of sulfate concentrations at the BABs wells as they are well below the site-wide upgradient maximum background concentrations observed at monitoring wells located at the BRPP site.

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

Further, as discussed above, more than 80 feet of native low hydraulic conductivity clay separates the BABs from the uppermost aquifer. Therefore, it would take far longer than the time that the BABs have been active (over 1,000 years) for any potential leak to migrate to the uppermost aquifer. This is supported by the information included in the Application, in the PALD (Attachment A), in the final ALD (Attachment B) and in the Aquifer Characterization Study (Attachment C) that support that the low hydraulic conductivity soils are an effective glacially-compacted natural clay liner system and that the uppermost aquifer is not in communication with the BABs CCR unit and the uppermost aquifer has not been affected by CCR management at the facility.

#### **e. The Monitoring Status is Adequate**

The data provided to EPA in the Applications, and the additional clarifications in this letter and the documentation provided in the ALDs and Aquifer Characterization Studies, continue to confirm that the clay is laterally continuous across the base of the BABs and DB, the uppermost aquifer is hydraulically separated from the BABs and DB, and that the aquifer remains unaffected by CCR operations. DTE has unequivocally demonstrated that the BABs and DB remains in detection monitoring and that the presence of Appendix III parameters in groundwater in the uppermost aquifer are geogenic. It is also recognized, and has been further explained above, that significant spatial variability is observed for most of the Appendix III parameters. The presence and distribution of these Appendix III constituents are attributable to variations in natural conditions that influence groundwater chemistry across the uppermost aquifer, which contributes to the variability in concentrations such as chloride and boron from well to well. The Unified Guidance is very clear that interwell methods are invalidated due to significant spatial variability, in addition to extremely slow horizontal groundwater flow rates and/or lack of definable flow path that make it impossible to compare upgradient to downgradient concentrations for compliance. It has been demonstrated that the SSIs for TDS at MW-16-01 and sulfate at MW-16-04 that prompted the ASD performed in August 2019 are not indicative of release from the BABs to the uppermost aquifer. Additional characterization studies continue to demonstrate that the uppermost aquifer beneath the BABs is unaffected by CCR management at

## DTE Electric Comments

EPA-HQ-OLEM-2021-0282

April 10, 2023

the facility. Further, there have been no SSIs recorded at the DB. Therefore, as clarified and further demonstrated above, the site data and compliance records show that the BABs and DB remains appropriately in detection monitoring.

EPA presented a hypothetical and erroneous statistical analysis in the Proposed Decision<sup>61</sup> that inaccurately alleges the DB is leaking. While EPA did not provide sufficient support for DTE to perform a comprehensive review, it appears that EPA's hypothetical statistical analyses are not valid in the context of the site-specific hydrogeological conditions that are observed at the BABs and DB. The details of these hydrogeological conditions and how they have shaped the monitoring network design and statistical analysis program are presented in detail in the Application and have been further clarified above throughout this letter. Although the EPA's analysis was misleading, no SSIs were identified, yet EPA goes on to speculate that sulfate at MW-16-10 is indicative of leakage from the DB, despite no SSIs being found.<sup>62</sup> This is another example of how EPA's review of the Applications selectively uses methods that conflict with their own guidance and the data provided to them in the Application. In this case, they generated misleading statistical analyses based on an exaggeration and misrepresentation of the data taken out of context that, even when those analyses indicate compliance was met (i.e., no SSIs compared to "background"), EPA somehow concluded that compliance was not met. In doing so, EPA has shown that it is not possible to comply with the standards of 40 C.F.R. §§ 257.93-257.94 and the Part B rule, in any scenario. DTE has demonstrated compliance with the CCR rule and has done so in good faith with qualified professional experience that aligns with industry standards. EPA's Proposed Decision contradicts their own statement that, "the determination will be prospective only; accordingly, for purposes of the ALD process, EPA is only interested in the state of a facility's current compliance rather than any instances of historic non-compliance."<sup>63</sup> As further demonstrated above, DTE's Applications provided the necessary information required under 40 C.F.R. §

April 10, 2023

257.71(d)(1)(i)(B)(2) that demonstrate compliance with of 40 C.F.R. §§ 257.93-257.94 and that both units appropriately remain in detection monitoring.

**C. Documentation of Unstable Areas is Sufficient Pursuant to 40 C.F.R § 257.64**

DTE previously documented that the BABs and DB are in stable area(s) and meet the requirements of 40 C.F.R. § 257.64 as described in the Appendix J of the Application and provides further clarification below in this section. Based on review of the Proposed Decision, there are conflicting statements from EPA regarding the documentation of unstable areas pursuant to 40 C.F.R § 257.64. In the Proposed Decision, EPA states: “The location restriction report refers to geotechnical explorations that identified more than 130 feet (for the DB) and 90 feet (for the BABs) thick clay with silt and sand lenses over soft to very hard shale bedrock, which can be confirmed by boring logs and cross-sections. The report does not sufficiently discuss the settling potential of the thick clays underlying the unit. ***However, because the impoundment is unlined, the differential settlement is unlikely to cause any major issues to the impoundment integrity*** [emphasis added]. Based on this review, EPA is proposing to conclude that the DB and BABs do not meet the location restriction in 40 C.F.R. § 257.64<sup>64</sup> for unstable areas. The bolded statement above suggests that EPA agrees with DTE’s conclusion that the impoundments are stable. There were separate reports prepared by TRC and included as Appendix J in the Applications that demonstrate that the BABs and the DB CCR units are not constructed in unstable areas and meet the location restriction criteria of 40 C.F.R. § 257.64. However, only one report is referenced by EPA in the above statement, so it is not entirely clear which report or which CCR unit requires more clarification.

Regardless, of this noted discrepancy, when determining whether an area is unstable, at a minimum the three factors discussed below must be considered pursuant to 40 C.F.R. § 257.64. As such, the following discussion is provided to document that the BABs and DB, underlain by a substantially thick laterally-continuous glacially-compacted clay, are in stable area(s) and meet the requirements of 40 C.F.R. § 257.64:

## DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

- **On-site or local soil conditions that may result in significant differential**

**settling:** As the BABs and DB are incised, additional pressures have not been placed on the native soils. When soil is excavated for a foundation, there is a reduction of stress (load) at the founding level. However, with the reduced load, the founding soil does not “rebound”. When the new foundation load is applied, settlement will not occur unless more load is added than was removed. The additional foundation load could bring the founding level up to its original stress condition and if the additional foundation load is greater than the original stress condition, settlement could occur, whether differential or uniform. The DB and BABs were constructed by excavating approximately 12 ft of clay soil to reach the foundation bottom grade. With a typical soil unit weight of 120 pounds per cubic foot (pcf), this represents the reduction of stress/load of 1,200 pcf. The soil conditions at these foundation depths and below are uniform as shown in the boring logs included in Appendices B and K in the Applications and Appendices B through E in the PALDs and final ALDs. Therefore, even if sufficient load were applied to cause settlement, differential settlement will not occur because the soil conditions are consistent across the CCR units.

The native soils are made up of soft to medium stiff clays to a depth of approximately 40 feet followed by medium to very stiff clays with sand inclusions. Excavations would have occurred into the unconsolidated clays to construct the basin. Bottom ash material and leachate (or water) would produce less pressure (lower effective stress) than what was formerly naturally occurring above the in-situ soils at depth, therefore, significant settlement is not anticipated.

- **On-site or local geologic or geomorphologic features:** No evidence of karst features or unstable bedrock was observed in the multiple geotechnical and environmental investigations undertaken historically at this site, most recently in December 2020 (see November 2021 BABs and DB PALDs). Voids were not observed or logged in the geotechnical investigations or during well installation around the basins, and bedrock was not observed until a depth of ~140 ft bgs. Additionally, as shown below in the FEMA-developed seismic design map, there is a very low seismic hazard for the site given that the assigned earthquake hazard seismic design category is white (or

Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

“A”) which exhibits a “very small probability of experiencing damaging earthquake effects”.<sup>65</sup>

- **On-site or local human-made features or events (both surface and subsurface):**

No historical human-made features, structures, or events have taken place at the site that would suggest instability. The BABs and DB are relatively isolated on site with no significant structures located adjacent to the BABs or the DB that could alter the conditions of the basins.

<sup>65</sup> [https://www.fema.gov/sites/default/files/2020-07/fema\\_hazard\\_maps\\_eastern-map\\_graphic.jpg](https://www.fema.gov/sites/default/files/2020-07/fema_hazard_maps_eastern-map_graphic.jpg)

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

The information provided in the Applications, and the above further clarifications, show that the BABs and DB are located in stable area(s) and meet the requirements of 40 C.F.R. § 257.64.

**D. DTE Has Provided Documentation of the Necessary Soil Characteristics and Engineering Quality to Perform the Demonstration**

The Application was prepared to meet the requirement of the Rule and was viewed as an application to get to the next step to perform the rigorous demonstration, assuming that, like a typical application process, there would be some back-and-forth communication and any questions EPA had from review of the application would be addressed through the demonstration. Several comments in the Proposed Decision refer to missing or inadequate information that prevented EPA from being able to make a determination (therefore used as a basis for denial). However, many of those items were part of step 2 of the Part B process (to be completed during the rigorous field testing in the demonstration) or were succinctly included in the application to satisfy EPA's request in the Part B Preamble to keep the applications concise.<sup>66</sup> The November 2020 PALDs (for both BAB and DB) were updated and finalized following the two-year compatibility testing and is included as the April 2022 ALD (for both BAB and DB) and included as Attachment B.

EPA stated in its Proposed Decision that DTE failed to demonstrate that the BABs and DB CCR units have a liner that is of good quality and in line with proven and accepted engineering practices, as required by 40 C.F.R. § 257.71(d)(1)(i)(C). 40 C.F.R. § 257.71(d)(1)(i)(C), states that "Documentation of the design specifications for any engineered liner components, as well as all data and analyses the owner or operator of the CCR surface impoundment relied on when determining that the materials are suitable for use and that the construction of the liner is of good quality and in-line with proven and accepted engineering practices."

A significant amount of data was collected on the physical properties of the soil before the BABs and DB were constructed and more was collected later as part of the monitoring well network installation that was referenced and included in the Application as Appendices A, B and K (including the Bechtel 1976 Subsurface Investigation and Foundation Report for Belle

Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

River Units 1&2, the TRC October 2017 Groundwater Monitoring Systems Summary Reports (BABs and DB) and the TRC December 2018 Natural Clay Liner Equivalency Evaluation Report). This included presenting that the glacially-compacted natural clay liner system is at least 80 feet thick and has a hydraulic conductivity ranging from  $2.1 \times 10^{-8}$  cm/s to  $2.9 \times 10^{-8}$  cm/s based on the dataset provided in the Applications. A significant amount of additional data was collected on the physical properties of the soil and was presented within the PALDs that were submitted to EPA on November 30, 2021 (Attachment A of this letter), more than a year before EPA rendered the Proposed Decision. The BABs and DB PALDs have been updated by Geosyntec to include additional hydraulic conductivity data from samples that were very slow in moving to termination criteria due to the low hydraulic conductivity and are attached as part of this comment package (Attachment B of this letter).

The BABs and DB preliminary PALDs and final ALDs demonstrate that the low permeability natural clay soils underlying the BRPP BABs and DB are consistently present across the units and have a thickness and sufficiently low hydraulic conductivity to prevent groundwater contamination throughout the active life of the unit<sup>67</sup>. Lab testing performed in accordance with the requirements of 40 C.F.R. § 257.71(d) had hydraulic conductivities ranging from  $4.4 \times 10^{-9}$  cm/s to  $2.1 \times 10^{-8}$  (similar to or lower than measured in previous testing). This range of hydraulic conductivity of the natural clay liner is well below the threshold to be considered for an ALD as EPA states, “[r]egardless, a conductivity of  $1 \times 10^{-7}$  cm/s for the lowermost soil component of the liner, whether in isolation or beneath a geomembrane component, remains the absolute floor for any unit to even be considered for an alternate liner demonstration.”<sup>68</sup>

In the Part B preamble, EPA recognizes that natural clay-rich soils are capable of achieving the required effective hydraulic conductivities lower than  $1 \times 10^{-8}$  cm/s and/or on a case-by-case basis may exhibit an adequate thickness of low-conductivity soil that supports having somewhat higher soil conductivities throughout or in a portion of the soil column. As stated in the Part B preamble, “EPA identified risks slightly above the relevant risk criteria only for lithium, one of the most mobile CCR constituents. Based on these model results,

<sup>68</sup> Part B Preamble at 72509

## DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

an effective hydraulic conductivity of  $1 \times 10^{-8}$  cm/s would be sufficient to reduce identified risks to below levels of concern on a national scale. However, **conditions present at individual facilities, such as the thickness of the low-conductivity soil** or the presence of a geomembrane liner, **might support somewhat higher soil conductivities on a case-by-case basis [emphasis added].**<sup>69</sup> In the case of the BRPP BABs and DB, the minimum clay thickness is at least 82 feet (below BABs) and 120 feet (below DB) of laterally contiguous clay, at least 26x the minimum design standard thickness of 3 feet for clay-lined units outlined in the 2015 CCR Rule.

Therefore, based on the above factors the BABs and DB CCR units have documentation of necessary soil characteristics and engineering quality to perform the ALDs and, in fact, with the ALDs already having been completed, meet the requirements of 40 C.F.R. § 257.71(d). This is based on the construction of the BABs and DB CCR units and surrounding site conditions, that there is no reasonable probability that continued operation of the BABs and DB surface impoundments will result in adverse effects to human health or the environment.

In addition to the comprehensive information provided in the Application and summarized above, the following additional lines of evidence generated as part of completing the ALD supports that the glacially-compacted natural clay liner system beneath the BABs and DB exceed the minimum standards of the Part B rule.

### **1. Good Quality Liner Materials and Construction**

The field investigations from the 1970s, 2016, and 2020 demonstrate that the subsurface lithology is consistent with low hydraulic conductivity clay-rich deposits with discontinuous sand seams at greater depths. Within the BABs and DB CCR units, the uppermost aquifer unit is present directly above the bedrock and appears to decrease in thickness and increase in silt content from west to east/southeast across the BABs and DB CCR units. A three-dimensional (3D) environmental visualization system (EVS) model using Earth Volumetric Studio software was used to visualize the significant amount of data (e.g. geology, geotechnical sample locations, monitoring well and well screen locations, and groundwater elevation surfaces) to visualize the extent of the

April 10, 2023

ponded water along with the geology. Lithologic cross-sections were created from the EVS models and analyzed to determine the various changes in lithology across the site, visualize model inputs, and estimate thicknesses of geologic layers.

#### *i. BAB CCR Unit Summary:*

Specific to the BABs, an EVS model was created and analyzed to determine the various changes in lithology within the clay confining unit directly underlying the BABs and the characteristics of the uppermost aquifer which sits directly above the bedrock. Upon review of the transects, the lithology beneath the BABs consists of (from the ground surface down) clay, clay with sand, uppermost aquifer, and shale bedrock. These units are consistent with historical reports and the Application. Based on Cone Penetrometer Test (CPT) and geotechnical index testing during the 2020 ALD investigation, the lithology directly underlying the BABs consists of the following:

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin

#### Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

- Clay – 50 to 60 ft thick directly beneath the BABs. This unit consists of mainly soft to medium stiff clay and minimal sand seams. None of the sand seams are interconnected or considered an aquifer unit.
- Clay with sand – This unit was encountered at approximately 50 to 60 ft bgs. With increasing thickness from west to east. At the west end of the BABs, this unit is approximately 40 ft thick and increases in thickness to 80 ft thick at the eastern edge of the BABs. This unit consists of stiffer gray clay with increasing sand seams. Although there are more frequent sand seams, most are less than 1-ft in thickness and have hydraulic conductivity values greater than  $1.0 \times 10^{-7}$  cm/s except for one location which is discussed in more detail below. The data supports that none of the sand seams are interconnected or considered an aquifer unit. Consequently, because the sands are isolated, the unit behaves like a low hydraulic conductivity clay unit.
- Uppermost Aquifer Unit – This unit was encountered at approximately 90 ft bgs in the west and increases in depth to 140 ft bgs in the east. The thickness of the unit corresponds to the overlying unit and thins from west to east and directly overlies the shale bedrock. The thickness changes from approximately 50 ft thick in the western edge of the BABs to 10 ft thick in the eastern/southeastern edge of the BABs. This sandy unit is saturated and considered the uppermost aquifer unit within the BABs CCR unit. There is a transition from sandy aquifer beneath the BABs CCR unit to a thin saturated silty aquifer south/southeast of the BABs. Specifically, this silty aquifer extends beneath the DB and both are considered the “uppermost aquifer unit” on the cross sections and within the EVS model.
- Shale bedrock – This unit was encountered at approximately 140-150 ft bgs.

During the 2020 ALD investigation, CPT borings were completed, and PPD tests were performed at CPT-01B, CPT-03, and CPT-06 to estimate the hydraulic conductivity of the lithology. In addition, laboratory testing was conducted on individual grab samples from the three sonic borings around BABs for long-term

## DTE Electric Comments

Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

breakthrough potential. Based on the review of the PPD Test data, values ranged between  $9.76 \times 10^{-9}$  cm/s and  $2.81 \times 10^{-6}$  cm/s. The CPT-derived highest hydraulic conductivity value of  $2.81 \times 10^{-6}$  cm/s was calculated at CPT-03 from a sand seam at 510 ft above mean sea level (AMSL) (approximately 80 ft bgs) within the clay with sand unit. PPD tests at CPT-03 directly above and below the sand seam indicated hydraulic conductivities less than  $1.0 \times 10^{-7}$  cm/s. Therefore, the (1) clay and clay with sand lithologies beneath the BABs have adequate hydraulic conductivity values to be considered a low hydraulic conductivity unit and is consistent with the 2018 Natural Clay Liner Equivalency Evaluation Report (Appendix A in the Application).

The EPA stated that the Application did not provide field data to demonstrate whether "...secondary porosity may be the primary driver of subsurface flow" and "...without field measurements to confirm reported laboratory measurements, there remains considerable uncertainty whether any existing or additional laboratory data collected in support of the demonstration is representative of actual liner performance."<sup>70</sup> However, it is the alternate liner demonstration (step 2), not the application (step 1) that is intended to prove the clay material can be considered suitable for use.<sup>71</sup> In addition, horizontal hydraulic conductivity was measured in over 28 pore pressure dissipation tests (PPDs) in the CPTs conducted for the alternate liner demonstration investigation and included in the PALD and final ALD. The results indicate that the horizontal hydraulic conductivities calculated from the PPDs exhibit similar results as vertical hydraulic conductivities, with consideration of secondary porosity, and is not a preferential transport mechanism.

Below the clay with sand is the uppermost aquifer unit that mainly consists of sand. This unit directly overlies the Bedford shale and decreases in thickness from west to south/southeast across the BABs. In the western portion of the BABs, the uppermost aquifer unit is approximately 50 ft thick (near MW-16-01) and thins to approximately 10 ft thick to the southeast. Beyond the BABs CCR

 Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

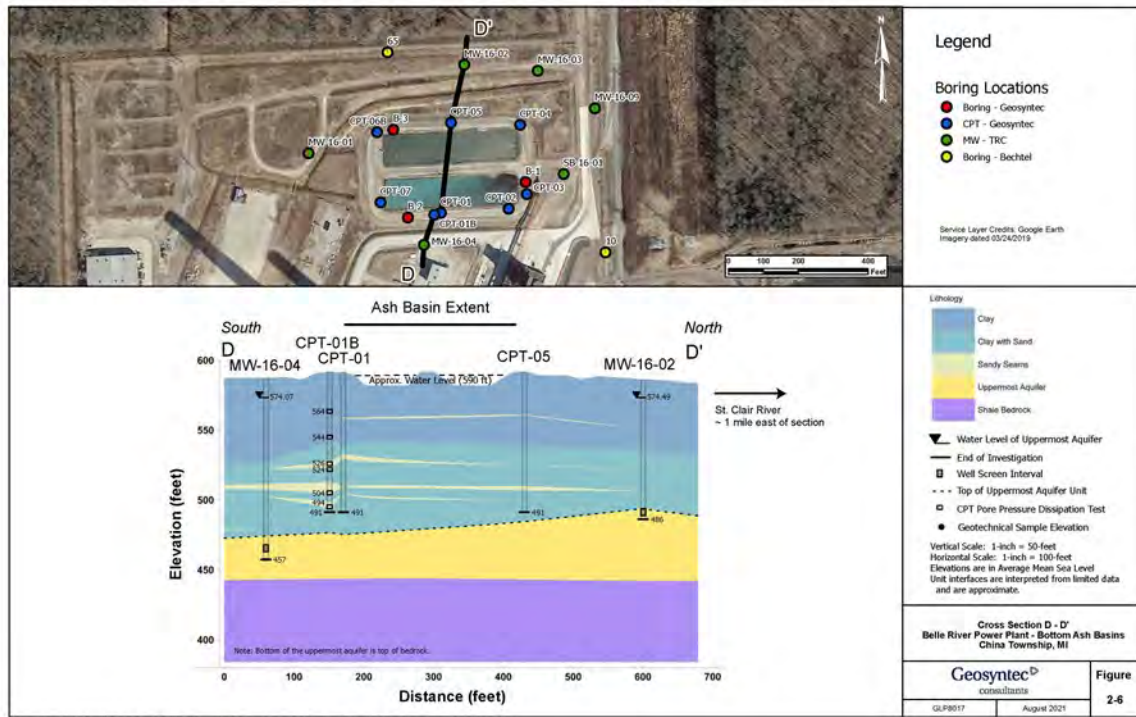

April 10, 2023

unit, the EVS model predicts this unit extending to the DB with increasing fines/silts. The hydraulic head in the uppermost aquifer unit associated with the BABs is approximately 574 ft AMSL with an almost flat horizontal gradient.

The bottom of the BABs is at an elevation of approximately 580 ft and the bottom of the clay underlying the BABs is at an elevation of approximately 500 ft (western portion), thus more than 80 ft of low hydraulic conductivity clay-rich deposits (clay and clay with sand) separate the bottom of the BABs from the underlying uppermost aquifer unit. Cross-sections were created from the EVS model and analyzed to determine the various changes in lithology across the site, visualize model inputs, and estimate thicknesses of geologic layers, as shown below and in Attachments A and B.

DTE Electric Comments  
Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications  
EPA-HQ-OLEM-2021-0282  
April 10, 2023

ii. DB CCR Unit Summary:

The lithology beneath the DB consists of (from the ground surface down) clay, clay with sand, uppermost aquifer unit, and shale bedrock. These units are consistent with historical reports and data presented in the Application. Based on CPT and geotechnical index testing during the 2020 ALD investigation, the lithology directly underlying the DB consists of the following:

- o Clay – 35 to 40 ft thick directly beneath the DB. This unit consists of mainly soft to medium stiff clay and minimal sand seams. None of the sand seams are interconnected or considered an aquifer unit.
- o Clay with sand – This unit was encountered at approximately 35 to 40 ft bgs with a thickness of approximately 80 to 90 ft. This unit consists of stiffer gray clay with increasing sand seams. Although there are more frequent sand seams, most are less than 2 ft in thickness and have hydraulic conductivity values less than  $1.0 \times 10^{-7}$  cm/s except for one location which is discussed in more detail below. The data supports that none of the sand

## DTE Electric Comments

EPA-HQ-OLEM-2021-0282

April 10, 2023

seams are interconnected or considered an aquifer unit. Consequently, because the sands are isolated, the unit behaves like a low hydraulic conductivity clay unit.

- Uppermost Aquifer Unit –This unit was encountered at approximately 130 to 145 ft bgs. The thickness of the unit is relatively consistent at 3 to 5-ft thick and directly sits atop the bedrock. This silty unit is saturated and considered the uppermost aquifer unit within the DB. There is a transition from the silty aquifer beneath the DB to a thicker sandy aquifer beneath the BABs located to the north/northwest of the DB. Both are considered the “uppermost aquifer unit” on the cross sections and within the EVS model.
- Shale bedrock – This unit was encountered at approximately 135-150 ft bgs.

During the 2020 ALD investigation, CPT borings were conducted and PPD tests were performed at CPT-08B, CPT-08C, CPT-11, CPT-12 and CPT-13B to estimate the hydraulic conductivity of the lithology. In addition, laboratory testing was conducted on individual grab samples from the three sonic borings around DB for long-term breakthrough potential. Based on the review of the PPD test data, values ranged between  $7.97 \times 10^{-9}$  cm/s and  $1.63 \times 10^{-6}$  cm/s around the DB. The CPT-derived highest hydraulic conductivity value of  $1.63 \times 10^{-6}$  cm/s was calculated at CPT-13B from an isolated sand seam at 490 feet above mean sea level (ft AMSL) (approximately 100 ft bgs) within the clay with sand unit. PPD tests at CPT-13 and CPT-12 located next to CPT-13B indicated hydraulic conductivities less than  $1.0 \times 10^{-7}$  cm/s. Therefore, the clay and clay with sand lithologies beneath the DB have adequate hydraulic conductivity values to be considered a low hydraulic conductivity unit and is consistent with the 2018 Natural Clay Liner Equivalency Evaluation Report (Appendix A in the Application).

Below the clay with sand is the uppermost aquifer unit that mainly consists of silt. This unit directly overlies the Bedford shale. Beyond the DB, the EVS model predicts this unit extending to the BABs with increasing sands. The

DTE Electric Comments

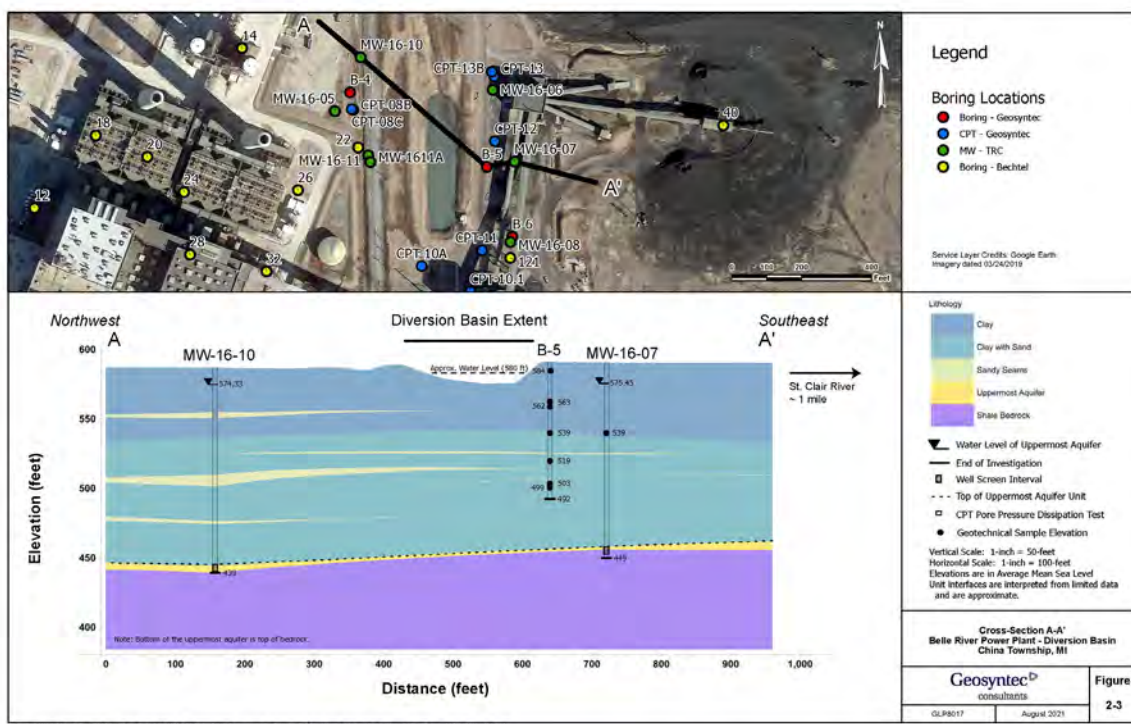

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

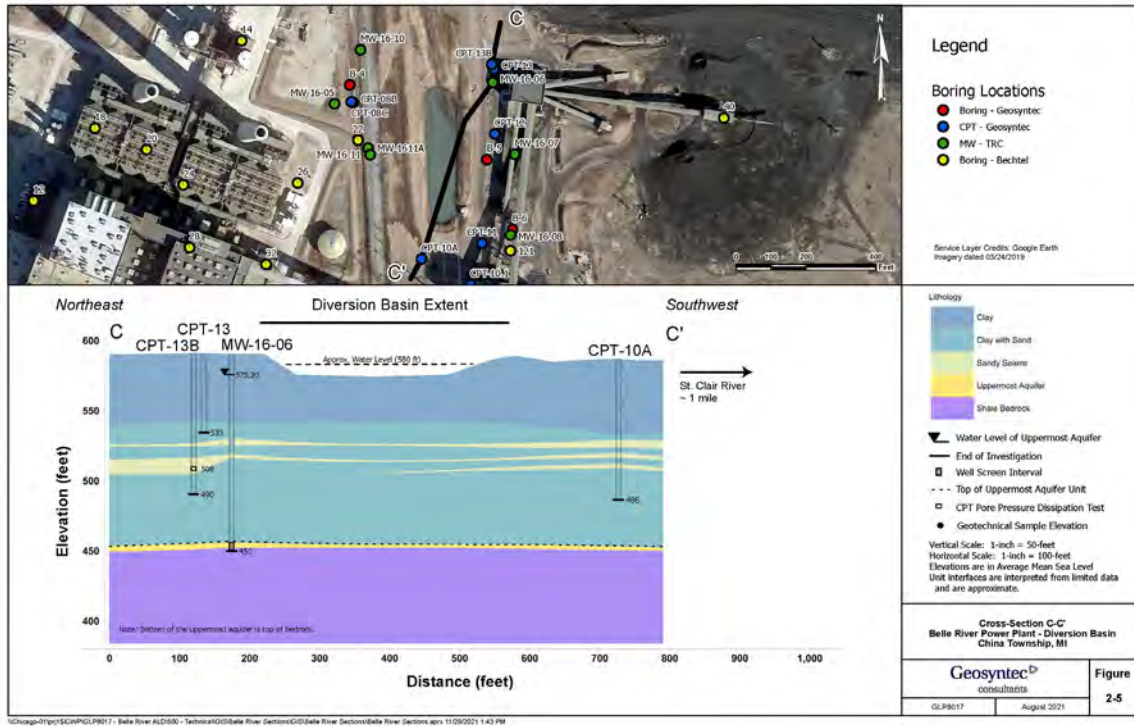

EPA-HQ-OLEM-2021-0282

April 10, 2023

hydraulic head in the uppermost aquifer unit associated with the DB is approximately 575 ft AMSL with a gradient to the west-northwest.

The bottom of the DB is at an elevation of approximately 576 ft AMSL and the bottom of the clay underlying the DB is at an elevation of approximately 450 ft AMSL, thus more than 120 ft of low hydraulic conductivity clay-rich deposits (clay and clay with sand) separate the bottom of the DB from the underlying uppermost aquifer unit. Cross-sections were created from the EVS model and analyzed to determine the various changes in lithology across the site, visualize model inputs, and estimate thicknesses of geologic layers, as shown below and in Attachments A and B:

## 2. Detailed Site Characterization Data Affirms the Conceptual Site Model

A host of data from three separate investigations was used to characterize the subsurface stratigraphy and soil characteristics for the BABs and DB CCR units. Historical investigations included a 1973-1974 investigation performed by Bechtel and a 2016 investigation performed by TRC, all of which are included in the Application. Data from the 2020 ALD Investigation performed by Geosyntec was used to supplement the data set. In total, these three investigations included 56 investigative locations that included 22 soil borings, 13 monitoring wells and 16 CPTs. These investigations extend across the site and include the BABs and DB, which is approximately 400 ft southeast of the BABs. Considering the proximity of both CCR units, field investigation data is used for both the BABs and DB.

Field testing included pocket penetrometer tests on fine-grained soils, slug tests for the monitoring wells screened in the uppermost aquifer, and PPDs tests at CPT locations. Lab testing included grain size distributions, Atterberg limits, water content, dry and/or total unit weight, specific gravity, and hydraulic conductivity testing. Laboratory and

## DTE Electric Comments

### Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

field test results are provided in the PALD and final ALD for the 1970s, 2016, and 2020 laboratory studies, respectively.

Data from 56 investigative locations that included 22 soil borings, 13 monitoring wells and 16 CPTs were reviewed and cataloged in a database for input to the 3D EVS model as shown in the cross-sections shown above and in Attachment A and B. In total, over 500 datapoints were utilized to create the 3D EVS model.

Hydraulic conductivity compatibility testing was completed in general accordance with "*Standard Test Method for Hydraulic Conductivity Compatibility Testing of Soils with Aqueous Solutions*", ASTM D7100, using site-specific contact water. The use of ASTM D7100 is discussed in the preamble of the CCR Rule and deemed appropriate by EPA.

Hydraulic conductivity testing on 14 soil samples were completed using deionized water in accordance with "*Standard Test Methods for Measurement of Hydraulic Conductivity of Saturated Porous Materials Using a Flexible Wall Permeameter*", ASTM D5084, to establish baseline K measurements. Then, to further characterize the range of hydraulic conductivity values six of the samples exhibiting high and low K values were selected for compatibility testing in accordance with ASTM D7100 using site-specific water from the pond (a.k.a, "contact water"). The testing ran continuously by Excel Geotechnical Testing, Inc. located in Roswell, GA for approximately two years for each of the samples. The final hydraulic conductivities ranged from between  $4.4 \times 10^{-9}$  cm/s and  $2.1 \times 10^{-8}$  cm/s. The longevity of the testing program was driven by the termination criteria of ASTM D7100 as fully described in the final ALD. Because of the consistency of the hydraulic conductivity results over the length of test duration (over two years), the testing demonstrated the lack of impact of contact water on the clay samples. All data associated with the hydraulic testing is summarized in detail in the PALD and final ALD Reports.

As detailed in the PALD and final ALD reports, in accordance with the demonstration requirements defined in 40 CFR § 257.71(d)(1)(ii), a fate and transport model analysis was performed to evaluate whether the peak groundwater concentrations that may result from releases to the groundwater from the BABs and DB CCR units exceeds the GWPS at the waste boundary throughout its active life. The model was run for the

DTE Electric Comments

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin

Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

operating period of 55 years. This modeling period captures the amount of time elapsed from the 1980s, when operations started at the BABs and DB, to 2034, which is the end of the projected active life of the BABs and DB CCR units after which they will be closed by removal. The results of the model predict constituent of concern concentrations that are very low such that there is no reasonable probability that water from BABs and DB CCR units will cause releases to groundwater throughout its active life that will exceed the groundwater protection standard at the solid waste boundary.

Therefore, as presented above, the BABs and DB CCR units have a liner that is of good quality and in line with proven and accepted engineering practices, as required by 40 C.F.R. § 257.71(d)(1)(i)(C). This is based on:

- The wealth of information provided in the Application and the additional supplemental information provided herein on the glacially-compacted natural clay liner system that demonstrate the performance of the soils underlying the BABs and DB meet the Part B requirements.
- Extensive and lengthy compatibility testing of the native clay materials will not degrade over time, further indicating its suitability as an alternate liner system.

The fate and transport modeling demonstrates that the water in the BABs and DB is not expected to reach the bedrock below the BABs and DB CCR units for more than 1,000 years, far beyond the active life of the BABs and DB CCR units of 55 years. Therefore, there is no reasonable probability that continued operation of the surface impoundment will result in adverse effects to human health or the environment even using elevated (conservative) Darcy velocities/hydraulic conductivities. Therefore, upon review of the multiple lines of evidence, the BABs and DB CCR units have a liner that is of good quality and in line with proven and accepted engineering practices, as required by 40 C.F.R. § 257.71(d)(1)(i)(C). These data were presented in the Applications and supplemented by the attached PALDs (Attachment A) and are documented in the attached final ALD Reports (Attachment B).

Proposed Denial of the DTE Belle River Power Plant Bottom Ash Basins and Diversion Basin  
Alternate Liner Demonstration Applications

EPA-HQ-OLEM-2021-0282

April 10, 2023

## **IX. Closing**

DTE appreciates the opportunity to submit comments on the Proposed Decision and trusts that EPA will consider the science and the facts presented herein when making a final decision on the Applications. Data provided by DTE as part of the Application process, and subsequent data presented in the preliminary and final ALDs, as well as supplemental aquifer characterization clearly demonstrate that the BABs and DB CCR units have not impacted groundwater quality, the data demonstrate compliance with the CCR rule, and the natural soils underlying the site exceed the minimum requirements of the Part B rule. On this basis, DTE opposes the Proposed Decision, firmly stands behind its CCR compliance program and believes that EPA's proposed findings of noncompliance are in error and should be reconsidered in a full accounting of the record of evidence provided herein.

RE: Preliminary Alternate Liner Demonstration  
DTE Electric Company Belle River Power Plant  
Bottom Ash Basins Coal Combustion Residuals Unit  
4505 King Road, China Township, Michigan

Dear Administrator Regan:

The DTE Electric Company (DTE Electric) is submitting the enclosed preliminary Alternate Liner Demonstration (ALD) to the U.S. Environmental Protection Agency (EPA) as a “place holder” and out of an abundance of caution to meet the November 30, 2021 date for submitting ALDs under the Part B rule.

As EPA has publicly acknowledged, the EPA has experienced unanticipated internal delays in reviewing and making decisions on the Part B applications that were submitted a year ago on November 30, 2020, and that this extended delay has practically eliminated the timeframe contemplated in the Part B rule for facilities to prepare their ALDs. Given this, EPA explains on their CCR Part B Implementation web page that they intend to “take actions to ensure that any facility approved to conduct a demonstration has the same amount of time anticipated by the current regulation to initiate and complete the demonstration after an approval.”

DTE Electric appreciates EPA’s commitment to take this corrective action and believes it is both necessary and appropriate. Regardless of the Agency’s internal delays DTE Electric proceeded expeditiously with the hydrogeological site characterization and laboratory study as detailed in the September 1, 2021 extension request due to analytical limitations. The extension request detailed the compatibility laboratory testing program results as of late August 2021, and projected termination criteria to be met by March 23, 2022. EPA has not yet responded to the extension request.

The enclosed preliminary ALD prepared by Geosyntec using preliminary data, concludes that the low permeability natural clay soils underlying the Belle River Power Plant Bottom Ash Basins are consistently present across the basin and have sufficiently low hydraulic conductivity to prevent groundwater contamination at the solid waste boundary through the active life of the unit.

As allowed by the agency, electronic files were submitted to Richard Huggins, Mary Jackson, Michelle Long, and Jason Mills via email. If you have any questions regarding this submittal, please contact me at 313.235.0153 or [christopher.scieszka@dteenergy.com](mailto:christopher.scieszka@dteenergy.com)

Sincerely,

Christopher Scieszka  
Project Manager, Environmental Management and Safety, DTE Energy

## 1. INTRODUCTION

This report has been prepared to provide the Preliminary Alternate Liner Demonstration (ALD) of Belle River Power Plant Bottom Ash Basins (BABs), one of two coal combustion residuals (CCR) units at the site, in accordance with 40 CFR Part 257 as amended on November 20, 2020 (CCR Rule). **Figure 1-1** provides a site location.

This report concludes that there is no reasonable probability that water from BABs will cause releases to groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary over the projected active life of the CCR unit.

### 1.1 Background

DTE Electric Company (DTE) submitted the Alternate Liner Demonstration Application for BABs to the United States Environmental Protection Agency (USEPA) on November 30, 2020 [1] in accordance with the CCR Rule. Soon after, DTE started the field and laboratory investigation studies to meet the requirements of the CCR Rule.

One of the requirements of the CCR rule is to conduct hydraulic conductivity testing using site-specific permeant liquid. The CCR Rule acknowledges that these tests may last long such that the operator of the CCR unit may need to submit an extension request for the laboratory testing program, and submit a preliminary ALD.

DTE submitted an extension request due to “analytical limitation” under a separate cover, dated September 1, 2021 [2]. The extension request detailed the compatibility testing program results as of late August 2021, and projected termination criteria to be met by March 23, 2022. The EPA has not yet responded to the extension request.

### 1.2 Purpose

The purpose of this report is to provide ALD approach, analysis details, and present results based on available data in accordance with the CCR Rule. Although the Part B Rule does not require the submittal of a preliminary ALD by November 30, 2021 if an extension request is submitted in accordance with §257.71(d)(2)(ii)(A), DTE is providing this preliminary ALD as a “place holder” and out of an abundance of caution and with confidence in the performance of the liner system to comply with the requirement to submit an ALD by November 30, 2021. A final ALD will be submitted in accordance with the schedule expected to be included in the forthcoming EPA decisions.

### 1.3 Report Organization

The remainder of this report is organized as follows:

- Section 2 – provides the field and laboratory investigation details, information on site geology/hydrogeology, and conceptual site model details.
- Section 3 – provides results of hydraulic conductivity testing, termination criteria details, chemistry testing of site-specific water, and discussion of results.
- Section 4 – provides analysis approach, details, groundwater protection standards, and evaluation of results as to whether BABs meet the ALD requirement of the CCR Rule.
- Section 5 – provides a summary of the report.
- Section 6 – provides certification.
- Section 7 – provides references.

#### **1.4 Terms of Reference**

This report was prepared by Mike Coram C.P.G., Omer Bozok P.E., Jesse Varsho P.E., and reviewed by John Seymour, P.E. of Geosyntec.

## 2. CHARACTERIZATION OF SITE HYDROGEOLOGY

The CCR Rule requires the following:

*§257.71(d)(ii)(A) Characterization of site hydrogeology. A characterization of the variability of site-specific soil and hydrogeology surrounding the surface impoundment that will control the rate and direction of contaminant transport from the impoundment. The owner or operator must provide all of the following as part of this line of evidence:*

*(1) Measurements of the hydraulic conductivity in the uppermost aquifer from all monitoring wells associated with the impoundment(s) and discussion of the methods used to obtain these measurements;*

*(2) Measurements of the variability in subsurface soil characteristics collected from around the perimeter of the CCR surface impoundment to identify regions of substantially higher conductivity;*

*(3) Documentation that all sampling methods used are in line with recognized and generally accepted practices that can provide data at a spatial resolution necessary to adequately characterize the variability of subsurface conditions that will control contaminant transport;*

*(4) Explanation of how the specific number and location of samples collected are sufficient to capture subsurface variability if:*

*(i) Samples are advanced to a depth less than the top of the groundwater table or 20 ft beneath the bottom of the nearest water body, whichever is greater, and/or*

*(ii) Samples are spaced further apart than 200 ft around the impoundment perimeter;*

*(5) A narrative description of site geological history; and*

*(6) Conceptual site models with cross-sectional depictions of the site environmental sequence stratigraphy that include, at a minimum:*

*(i) The relative location of the impoundment with depth of ponded water noted;*

*(ii) Monitoring wells with screening depth noted;*

*(iii) Depiction of the location of other samples used in the development of the model;*

*(iv) The upper and lower limits of the uppermost aquifer across the site;*

*(v) The upper and lower limits of the depth to groundwater measured from monitoring wells if the uppermost aquifer is confined; and*

*(vi) Both the location and geometry of any nearby points of groundwater discharge or recharge (e.g., surface waterbodies) with potential to influence groundwater depth and flow measured around the unit.*

## **2.1 Introduction**

This section provides information on site geology and hydrogeology, data used in site characterization, a summary of ALD-specific field and laboratory study, and a conceptual site model built using the Environmental Visualization System (EVS).

## **2.2 Site Geology**

The surficial topography of St. Clair County is characterized by a low-relief floodplain, stream terrace, and lakeshore deposits. The subsurface geology of the area is defined by glacial deposits, which range in thickness from 100 to 400 ft thick. These glacial sediments, including lacustrine, till, and sand and gravel outwash deposits, were deposited on the underlying bedrock. Throughout St. Clair County the underlying bedrock varies but is primarily fine-grained siliclastic rock, mostly shale with some sandstone [1].

The St. Clair River is the major surface water body in the county and runs along the eastern boundary of the county. Shallow regional groundwater flow would be expected to be to the east towards the St. Clair River. The BABs CCR Unit is located approximately one mile west of the St. Clair River.

### **2.2.1 Bottom Ash Basin Site-Specific Geology**

The geology of St. Clair County consists of approximately 100 to 400 ft of glacial deposits, primarily lacustrine deposits, till, and, to a lesser extent, sand and gravel outwash, overlying a variety of bedrock surfaces. The glacial material underlying the BABs appears to be glaciolacustrine clays with local sand lenses. The uppermost aquifer unit (sandy rich interval) appears to be deposits from glaciofluvial outwash deposited directly above the bedrock surface.

The BABs CCR Unit is underlain by more than 100 ft of unconsolidated sediments, with the lower confining Bedford Shale generally encountered from 140 to 150 ft below ground surface (bgs). In general, the BABs CCR unit is initially underlain by approximately 90 ft in the western portion of the BABs and 130 ft in the eastern portion of the BABs of laterally extensive low hydraulic conductivity clay-rich deposits. During Geosyntec's ALD investigation in December 2020, cone

penetration test (CPT) dissipation tests were performed to determine hydraulic conductivity of the underlying clay-rich deposits, the results of the dissipation tests are summarized in Section 2.5.1. The CPT data confirm that the underlying deposits are consistently low hydraulic conductivity units.

The uppermost aquifer unit is a confined, sand-rich interval (within the footprint of the BABs) that directly overlies the Bedford Shale. It is thicker in the western portion of the BABs and decreases to the southeast. From west to east/southeast the uppermost aquifer increases in fines from a sandy unit to a silty unit. For the purposes of this report, the saturated unit directly overlaying the Bedford Shale (sandy and silty) is considered the “uppermost aquifer unit”. It is further discussed in **Section 2.6**.

### **2.3 Uppermost Aquifer Field Testing and Hydrogeology**

TRC calculated the hydraulic conductivities within the CCR monitoring wells set within the upper portion of the uppermost aquifer using single well hydraulic conductivity tests (e.g., slug tests) performed in 2016 and 2021 by TRC. Test results are provided in **Appendix A** and included in the EVS model. The monitoring well logs and construction details are presented in **Appendix B**. As calculated by TRC, the hydraulic conductivity of the uppermost aquifer using wells at the BABs CCR Unit area is approximately 1.2 ft/day (4E-4 cm/s).

### **2.4 Summary of Data Used for Site Characterization**

A host of data from three separate investigations was used to characterize the subsurface stratigraphy and soil characteristics for the site. Historical investigations included a 1973-1974 investigation performed by Bechtel and a 2016 investigation performed by TRC, all of which are included in the initial ALD Application [1]. Data from the 2020 ALD Investigation performed by Geosyntec was used to augment the data set. In total, these three investigations included 56 investigative locations that included 22 soil borings, 13 monitoring wells and 16 CPTs. **Figure 2-1** provides investigation locations.

Boring logs for the 1970s, 2016, and 2020 field investigations are provided in **Appendices C** through **E**, respectively. These investigations extend across the site and include BABs and Diversion Basin (DB), which is another CCR unit connected to BABs (~ 400 ft southeast of BABs). Considering the proximity of both CCR units, field investigation data is used for both CCR units.

Field testing included pocket penetrometer tests on fine-grained soils, slug tests for the monitoring wells screened in the uppermost aquifer, and pore pressure dissipation tests (PPDs) at CPT locations. Lab testing included grain size distributions, Atterberg limits, water content, dry and/or total unit weight, specific gravity, and hydraulic conductivity testing. Type of tests, standards and

number of tests are summarized in **Table 2-1**. Laboratory test results are provided in **Appendices F through H** for the 1970s, 2016, and 2020 laboratory studies, respectively.

Considering the extent of existing field investigation data, it is Geosyntec's opinion that the data used in building this model is sufficient to capture the variability that may exist in soil conditions.

## **2.5 ALD-Specific Site Investigation Details**

The scope of work for the ALD-Specific Site Investigation (SI) was completed in December 2020 and included drilling and sampling and advancing a CPT probe through the embankment and native soils. The purpose of the fieldwork was to obtain nominally undisturbed samples for hydraulic conductivity testing and to augment the existing data set to characterize the alternate liner materials in accordance with the CCR Rule. Investigations were conducted generally at 200-ft intervals but adjusted in the field as necessary to avoid underground utility lines, overhead power lines, and access issues, as needed. Investigations extended down to 100 ft bgs to an elevation approximately 490 ft, which is lower than groundwater level, and 20 ft below the nearest water body that is St. Clair River with a bottom elevation of approximately 525 ft.

The following sections provide a summary of the fieldwork completed during the SI.

### **2.5.1 Cone Penetrometer Tests**

Eight CPTs were completed around the berms of the BABs in 200 ft intervals to characterize the BABs embankment and native soils. Similarly, seven CPTs were completed around DB. The CPT locations are provided in **Figure 2-1**. CPTs were advanced from the ground surface to refusal or to approximately 100 ft bgs. Pore pressure dissipation tests were conducted to estimate in-situ hydraulic conductivity at select depths; at a minimum, these tests were conducted near the sonic borings and at the elevation near where undisturbed samples were collected for laboratory hydraulic conductivity testing.

In total, 16 dissipation tests were completed at CPTs advanced around BABs, and 12 dissipation tests were completed at CPTs advanced around DB. Hydraulic conductivity values were estimated to range between 9.76E-9 cm/s and 2.81E-6 cm/s around BABs, and range between 7.97E-9 cm/s and 1.63E-6 cm/s around DB. Hydraulic conductivity values are similar between soils underlying BABs and DB. Results are summarized in **Table 2-2**. These values are consistent with TRC's 2018 Natural Clay Liner Equivalency Evaluation Report [1]. CPT logs are provided in **Appendix I1**, and PPD tests are provided in **Appendix I2**.

### **2.5.2 Sonic Drilling**

In December 2020, six soil borings were advanced at the site to evaluate the subsurface geology, collect undisturbed samples for hydraulic conductivity testing, and collect additional soil samples

for characterization of native soils and the embankment. Soil samples were collected continuously in two to ten-foot sections from the ground surface to the termination of the soil boring. Geosyntec staff were present to log each boring and describe the soil samples in accordance with the Unified Soil Classification System (USCS). Shelby tubes were collected from the BABs embankment soils, and native soils at approximately 20 ft intervals from each of the sonic borings in accordance with ASTM D1587<sup>1</sup>. The soil borings were advanced to depths of approximately 100 ft-bgs to within the first encountered uppermost aquifer and/or into the top of the underlying shale bedrock. Sonic drilling locations are provided in **Figure 2-1**. Boring logs are provided in **Appendix E**. Soil stratigraphy is discussed in Section 2.6.

### 2.5.3 Laboratory Testing

A suite of index testing and hydraulic conductivity testing was conducted on select soil samples. Fourteen soil samples were collected from six borings for hydraulic conductivity testing from depths between five ft and 90 ft to capture soil conditions ranging from soft to very stiff soils. Details of hydraulic conductivity testing are provided in Section 3.

Index testing included:

- 24 Moisture Content tests (ASTM D2216)
- 4 Specific Gravity tests (ASTM D854)
- 22 Grain Size Mechanical Sieve tests (ASTM D6913)
- 21 Atterberg Limits tests (ASTM D4318)

Note that these tests quantities are included in **Table 2-1**. Test results are provided in **Appendix H**.

## 2.6 Conceptual Site Model

An EVS model was developed for the site based on data collected during the field investigations from the 1970s, 2016, and 2020. The EVS model centralized all the data to develop a comprehensive Conceptual Site Model (CMS). Based on the EVS model, the overall CMS of the Site lithology is relatively consistent with a low hydraulic conductivity clay-rich deposits with non-interconnected sand seams at deeper depths. Within the BABs CCR unit, the uppermost

---

<sup>1</sup> ASTM D1587 – Standard Practice for Thin-walled Tube Sampling for Fine-grained Soils.

aquifer unit sits directly above the bedrock and appears to thin and increase in silt from west to east/southeast across the BABs CCR unit.

Specific to the BABs CCR unit, Cross-sections (**Figures 2-2 through 2-7**) were created from the EVS model and analyzed to determine the various changes in lithology within the clay confining unit directly underlying the BABs and the characteristics of the upper aquifer unit which sits directly on the bedrock. Upon review of the transects, the lithology beneath the BABs consists of (from the ground surface down) (1) clay, (2) clay with sand, (3) uppermost aquifer unit, and (4) shale bedrock. These units are consistent with historical reports and TRC's November 2020, Initial Application for Alternate Liner Demonstration [1]. There were some discrepancies, in that the second clay unit was described as silty instead of sandy. Based on CPT and geotechnical index testing during Geosyntec's 2020 ALD investigation, the lower clay was re-interpreted as "clay with sand" mainly due to sand seams that were encountered. The clay within the "clay with sand" unit is relatively consistent stiff gray clay. Therefore, the lithology directly underlying the BABs consist of the following:

- (1) Clay – 50 to 60 ft thick directly beneath the BABs. This unit consists of mainly soft to medium stiff clay and minimal sand seams. None of the sand seams are interconnected or considered aquifer unit.
- (2) Clay with sand – This unit was encountered at approximately 50 to 60 ft bgs. Increasing thickness from west to east. At the west end of the BABs, this unit is approximately 40 ft thick and increases in thickness to 80 ft thick at the eastern edge of the BABs. This unit consists of stiffer gray clay with increasing sand seams. Although there are more frequent sand seams, most are less than 1 foot in thickness and have hydraulic conductivity values greater than  $1 \text{ E-7 cm/s}$  except for one location which is discussed in more detail below. The data supports that none of the sand seams are interconnected or considered an aquifer unit. Consequently, because the sands are isolated, the unit behaves like a low hydraulic conductivity clay unit.
- (3) Uppermost Aquifer Unit –This unit was encountered at approximately 90 ft bgs in the west and increases in depth to 140 ft bgs to the east. The thickness of the unit corresponds to the overlying unit and thins from west to east and directly sits atop the bedrock. The thickness changes from approximately 50 ft thick in the western edge of the BABs to ten ft thick in the eastern/southeastern edge of the BABs. This sandy unit is saturated and considered the uppermost aquifer unit within the BABs CCR unit. There is a transition from sandy aquifer beneath the BABs CCR unit to a thin saturated silty aquifer south/southeast of the BABs. Specifically, this silty aquifer extends beneath the DB and both are considered the "uppermost aquifer unit" on the cross sections and within the EVS model.

- (4) Shale bedrock – This unit was encountered at approximately 140-150 ft bgs.

During Geosyntec's 2020 investigation, CPT tests were conducted, and dissipation tests were completed at CPT-01B, CPT-03, and CPT-06 to estimate the hydraulic conductivity of the lithology. In addition, laboratory testing was conducted on individual grab samples from the three sonic borings around BABs for long-term breakthrough potential and is further discussed in Section 3. Based on the review of the CPT dissipation data (as discussed in Section 2.5.1 and Section 3), values ranged from  $9.76\text{E-}9$  cm/s to  $2.81\text{E-}6$  cm/s. The CPT-derived highest hydraulic conductivity value of  $2.81\text{E-}6$  cm/s was calculated at CPT-03 from a sand seam at 510 ft AMSL (approximately 80 ft bgs) within the (2) clay with sand unit. Dissipation tests at CPT-03 directly above and below the sand seam indicated hydraulic conductivities less than  $1\text{E-}7$  cm/s. Therefore, the (1) clay and (2) clay with sand lithologies beneath the BABs have adequate hydraulic conductivity values to be considered a low hydraulic conductivity unit and is consistent with TRC's 2018 Natural Clay Liner Equivalency Evaluation Report [1].

Below the clay with sand is the uppermost aquifer unit that mainly consists of sand. This unit directly overlies the Bedford shale and decreases in thickness from west to south/southeast across the BABs. In the western portion of the BABs, the uppermost aquifer unit is approximately 50 ft thick (near MW-16-01) and thins to approximately 10 ft thick to the southeast. Beyond the BABs CCR unit, the EVS model predicts this unit extending to the DB CCR unit with increasing fines/silts. The hydraulic head in the (3) uppermost aquifer unit associated with the BABs is approximately 574 ft AMSL (TRC 2018a) with an almost flat horizontal gradient.

The bottom of the BABs is at an elevation of approximately 580 ft and the bottom of the clay underlying the BABs is at an elevation of approximately 500 ft (western portion), thus more than 80 ft of low hydraulic conductivity clay-rich deposits ((1) clay and (2) clay with sand) separate the bottom of the BABs CCR unit from the underlying (3) uppermost aquifer unit.

### 3. POTENTIAL FOR INFILTRATION

The CCR Rule requires:

*§257.71(d)(ii)(B) Potential for infiltration. A characterization of the potential for infiltration through any soil-based liner components and/or naturally occurring soil that control release and transport of leachate. All samples collected in the field for measurement of saturated hydraulic conductivity must be sent to a certified laboratory for analysis under controlled conditions and analyzed using recognized and generally accepted methodology. Facilities must document how the selected method is designed to simulate on-site conditions. The owner or operator must also provide documentation of the following as part of this line of evidence:*

- (1) The location, number, depth, and spacing of samples relied upon is supported by the data collected in paragraph (d)(1)(ii)(A) of this section and is sufficient to capture the variability of saturated hydraulic conductivity for the soil-based liner components and/or naturally occurring soil;*
- (2) The liquid used to pre-hydrate the samples and measure long-term hydraulic conductivity reflects the pH and major ion composition of the CCR surface impoundment porewater;*
- (3) That samples intended to represent the hydraulic conductivity of naturally occurring soils (i.e., not mechanically compacted) are handled in a manner that will ensure the macrostructure of the soil is not disturbed during collection, transport, or analysis; and*
- (4) Any test for hydraulic conductivity relied upon includes, in addition to other relevant termination criteria specified by the method, criteria that equilibrium has been achieved between the inflow and outflow, within acceptable tolerance limits, for both electrical conductivity and pH.*

#### 3.1 Soil Sample and Site-Specific Water Details

##### 3.1.1 Soil Samples for Hydraulic Conductivity Testing

Fourteen soil samples were collected for hydraulic conductivity testing. Considering the extent of existing field investigation data, including CPTs, earlier borings, Geosyntec believes that the collected samples are sufficient to capture the variability of hydraulic conductivity in natural soils.

##### 3.1.2 Site-Specific Water Testing and Results

Site-specific CCR porewater samples were collected from both BABs and the DB for geochemical analyses to determine the representative composition of an “aggressive” solution for use in the

compatibility portion of the hydraulic conductivity testing. Due to the high turbidity of basin waters, samples were filtered through a 0.45-micron filter to evaluate dissolved concentrations. Site-specific water samples were tested for CCR Rule Appendix III and Appendix IV parameters as well as additional major cations (sodium, magnesium, potassium), anions (total alkalinity), iron, and manganese.

All water samples were found to be slightly basic, with pH concentrations ranging from 7.87 to 9.01 SU. TDS concentrations of all three samples are similar, ranging from 200 to 300 mg/L. All three samples have TDS concentrations < 1000 mg/L, which is defined by the United States Geological Survey (USGS) as “freshwater”. BABs and DB samples have similar major ion compositions, as illustrated on the Piper diagram in **Figure 3-1**. The anion composition is very similar for all three samples and consists of predominantly sulfate with some alkalinity and very little chloride. The cation composition is predominantly calcium and monovalent cations (potassium/sodium), with a smaller proportion of magnesium. The DB sample has a slightly higher relative percentage of calcium and lower monovalent cations compared to the BABs samples.

The analytical results are provided in **Appendix J** and tabulated in **Table 3-1**. Results were used to calculate total ionic strength for each sample. Total ionic strength is a measure of the combined ion concentrations in a solution and can represent the salinity of a sample. Total ionic strength was calculated for each sample using geochemical modeling software Geochemist’s Workbench (GWB) v12.0.4. The GWB thermodynamic dataset ‘thermo.com.V8.R6\_.tdat’ was used for the calculations in order to incorporate all tested parameters. Analytical results for each parameter were input into GWB in units of milligrams per liter (mg/L) and the ionic strength of each sample was calculated in units of molality (m).

Both BABs samples contained similar ionic strength values (0.0088 and 0.0080 m) compared to the slightly higher ionic strength of the DB sample (0.0106 m). Thus, the DB sample is considered to be the more aggressive solution and was used for compatibility testing as described in Section 3.2.

### **3.2 Hydraulic Conductivity Testing Procedure and Termination Criteria**

All 14 soil samples were tested for hydraulic conductivity,  $k$  using deionized water in accordance with ASTM D5084 [3] to establish a baseline  $k$  reading. Then, six of the samples exhibiting high and low  $k$  values were selected for compatibility testing in accordance with ASTM D7100 [4] using site-specific water. The use of ASTM D7100 is discussed in the preamble of the CCR Rule and deemed appropriate by USEPA.

ASTM D7100 termination criteria require the following conditions:

- The ratio of outflow to inflow is between 0.75 and 1.25. The hydraulic conductivity is considered steady if four or more consecutive hydraulic conductivity determinations fall within  $\pm 25\%$  or better of the mean value for hydraulic conductivity,  $k \geq 3E-8$  cm/s or within  $\pm 50\%$  or better for  $k < 1E-8$  cm/s, and a plot or tabulation of the hydraulic conductivity versus time shows no significant upward or downward trend;
- At least 2 pore volumes (PV) of flow have passed through the sample; and
- pH and electrical conductivity of effluent, is within 10% of that for the influent with no significant increasing or decreasing trends

### 3.3 Hydraulic Conductivity Test Results and Assessment

Preliminary results are provided in **Appendix K** as of August 20, 2021 and summarized in **Table 3-2**. The table provides sample ID, the start date for testing, amount of flow passed through a sample for a given duration of time, hydraulic conductivity values, and projected date for completing 2 PV of flow.

In addition, a set of figures created for each sample providing insight into the progression of:

- PV of flow with time.
- hydraulic conductivity with time.
- hydraulic conductivity with PV;
- pH of inflow and outflow with time; and
- Electrical conductivity (EC) with time.

Progression of different parameters is provided from **Figure 3-2** through **3-31**.

Overall, the hydraulic conductivity,  $k$  value of samples range between  $8.2E-09$  and  $2.8E-08$  (cm/s). The amount of PV of flow that has passed through the samples ranges from 0.8 to 2.3. As of August 20, 2021, two of the samples have reached the 2 PV criteria. The remaining samples are projected to reach 2 PV March 2022; this is based on linear extrapolation between PV at known dates and assumes  $k$  stays relatively constant. Overall, the PV of flow is progressing linearly towards the 2 PV criteria. Hydraulic conductivity values are generally flat and can be considered steady.

pH values are provided in **Table 3-3**. In general, the average pH of inflow ranges from 8.2 to 8.4, and the average pH of outflow ranges from 8.1 to 8.4. The pH of outflow is within 10 percent of inflow.

EC values are provided in **Table 3-4**. In general, the average EC of inflow ranges from 609 to 680, and the average EC of outflow ranges from 778 to 2146. The EC of outflow are not within the 10 percent of inflow; they are projected to meet the termination criterion by the end of December 2021. This date is based on the convergence of linear extrapolations of the data.

**Table 3-5** summarizes if the sample has reached the termination criterion for PV, pH, EC, and the approximate projected date for reaching the termination criteria. As summarized in the table, samples have not reached all the termination criteria; pH has achieved termination criterion, and two of the samples have reached the PV criterion; none of the samples have reached the EC criterion. Based on available data, Geosyntec expects the last sample to reach termination criteria by the end of March 23, 2022.

The results do not include inflow vs outflow data. The main reason is that the project team had decided to keep the inflow constant, which provides more stable gradient across the sample, more accurate estimation of  $k$ , faster testing, and more control in the testing procedure. It is Geosyntec's opinion that the inflow/outflow criterion would be reached by the time other criteria is reached.

#### 4. FATE AND TRANSPORT MODEL ANALYSES

The CCR Rule requires:

*§257.71(d)(ii) (C) Mathematical model to estimate the potential for releases. Owners or operators must incorporate the data collected for paragraphs (d)(1)(ii)(A) and (d)(1)(ii)(B) of this section into a mathematical model to calculate the potential groundwater concentrations that may result in downgradient wells as a result of the impoundment. Facilities must also, where available, incorporate the national-scale data on constituent concentrations and behavior provided by the existing risk record. Application of the model must account for the full range of site current and potential future conditions at and around the site to ensure that high-end groundwater concentrations have been effectively characterized. All the data and assumptions incorporated into the model must be documented and justified.*

*(1) The models relied upon in this paragraph (d)(1)(ii)(C) must be well- established and validated, with documentation that can be made available for public review.*

*(2) The owner or operator must use the models to demonstrate that, for each constituent in appendix IV of this part, there is no reasonable probability that the peak groundwater concentration that may result from releases to groundwater from the CCR surface impoundment throughout its active life will exceed the groundwater protection standard at the waste boundary.*

*(3) The demonstration must include the peak groundwater concentrations modeled for all constituents in appendix IV of this part attributed both to the impoundment in isolation and in addition to background.*

##### 4.1 Introduction

A fate and transport model analysis have been performed to evaluate whether the peak groundwater concentrations that may result from releases to the groundwater from the BABs exceeds the groundwater protection standards (GWPS) at the waste boundary throughout its active life.

The model considers flow of CCR pore water Constituents of Concern (COCs) migrating through the bottom of CCR unit down to the uppermost aquifer. The model does not consider additional migration of COCs horizontally to the waste management boundary. If considered, the horizontal groundwater flux would reduce the concentrations of the COCs; consequently, the model presents a conservative assessment. As discussed later in Section 4.6.1 the results of the model predicts COCs concentrations that are very low such that there is no reasonable probability that water from BABs will cause releases to groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary over the projected active life of the CCR unit.

## 4.2 Groundwater Protection Standards

Groundwater samples from TRC's 2016 and 2017 sampling events were tested for Appendix IV COC and represent eight rounds of background groundwater data. The data were used to calculate site-specific background levels (Background) for Appendix IV COC. **Appendix L** provides the memorandum describing the statistical calculations.

To develop GWPS for the ALD assessment, the federal Maximum Contaminant Level (MCL), Regional Screening Levels, and Background (whichever is higher) were evaluated and the highest value was selected as the GWPS in accordance with the CCR Rule. Where MCL are not available Regional Screening Levels were used. GWPS are provided in **Table 4-1**.

## 4.3 Consideration of Background Groundwater Concentrations

The background has been considered and is a factor when determining if GWPS has been exceeded. At the BABs, naturally occurring background concentrations are generally much lower than the GWPS. The predicted groundwater concentrations and peak groundwater background concentrations are further discussed in Section 4.6.1.

## 4.4 Leachate Quality Results

Porewater (i.e. leachate) quality samples from BABs and the DB were collected in December of 2020 and January of 2021; samples were analyzed for Appendix III and IV parameters by ALS Environmental in Holland, MI. Analytical results were compared for each parameter and the highest leachate concentration was used as the established concentration of the constituent ( $C_o$ ) when calculating the predicted groundwater concentrations ( $PGC_i$ ), as discussed further in this Section. The leachate quality data is summarized in **Table 4-2**.

In addition to the site-specific leachate concentrations, 90<sup>th</sup> percentile concentrations from the 2014 EPA study [5] were considered in the analysis. This data is summarized in **Table 4-2**.

## 4.5 Fate and Transport Model

### 4.5.1 Analysis Model

A one-dimensional fate and transport model was designed to further understand the potential for contaminant transport from the CCR units to the uppermost aquifer. The model was developed with a contaminant transport process through the clay and clay with sand layers under the BABs. Contaminant transport processes are discussed in Section 4.5.2.1 below.

The modeling program POLLUTE [6] was selected for the one-dimensional fate and transport evaluation. The data input for POLLUTE acquires all the input parameters, performs calculations

for individual transport processes, and then uses the semi-analytical solution for the various transportation process (see Section 4.5.2) to yield predicted concentrations at the various specified times and distances.

Model setup and inputs are discussed in detail in the following sections and are summarized via layers in **Figure 4-1**.

## 4.5.2 Proposed Mathematical and Associated Computer Model

### 4.5.2.1 *Mathematical Model*

The potential transport mechanisms that may occur at the BABs for the various modeled layers include advection, mechanical dispersion and diffusion. For porous media, these transport mechanisms can be represented by the following one-dimensional flow equation [7]:

$$\textbf{Equation No. 1:} \quad n \frac{\delta c}{\delta t} = nD \frac{\delta^2 c}{\delta z^2} - V_{\alpha} \frac{\delta c}{\delta z} - \rho K_d \frac{\delta c}{\delta t} - n\lambda c$$

Where:

c = concentration at any point

D = Coefficient of hydrodynamic dispersion in the vertical direction

n = porosity of the geologic layer

K<sub>d</sub> = distribution coefficient

V<sub>α</sub> = Darcy Velocity in the vertical direction

ρ = dry density of soil

λ = decay constant of the contaminant species

t = time

POLLUTE utilizes the transport phenomena as governed by Equation No. 1

### 4.5.2.2 *Predicted Groundwater Concentrations*

This model uses an initial concentration value of one (1), which represents a unit concentration of any constituent in the leachate. The results from the model can thus be used as a prediction factor for estimating the future concentration of any constituent of concern in groundwater. Multiplying the output prediction factor by the initial leachate concentration provides the predicted

groundwater concentration at the end of the model run. The following equation (Equation No. 2) illustrates this concept:

$$\textit{Equation No. 2:} \quad \text{PGC}_t = \text{PF}_t * \text{C}_o$$

Where:

$\text{PGC}_t$  = predicted groundwater concentration after t years.

$\text{PF}_t$  = prediction factored after t years, which is the output of the model.

$\text{C}_o$  = established leachate concentration of the constituent of concern.

### 4.5.3 Fate and Transport Model Inputs

#### 4.5.3.1 *Initial Leachate or Source Concentration*

The initial leachate concentration input value used was one (1). This value is unitless because it represents unit leachate concentration of any given constituent. Therefore, the model results represent a fraction of the initial leachate concentration for any constituent.

#### 4.5.3.2 *Number of Layers and Layer Thickness*

Two layers were modeled at the site: the clay layer and the clay with sand layer. At the BABs, the clay layer has an average thickness of 40 ft; the clay with sand layer has an average thickness of 63 ft. The average thickness of each layer was derived from an isopach map generated by subtracting the surface representing the bottom of the layer from the surface representing the top of the layer, and averaging the difference over the extent of the footprint of the BABs; model documentation for the average thickness of each layer can be found in **Appendix M**.

POLLUTE also allows layers to be subdivided into sublayers, which allows the predicted concentration distribution within a layer to be calculated. The clay layer was divided into 25 sublayers at the BABs. The clay with sand layer was divided into 40 sublayers at the BABs.

#### 4.5.3.3 *Modeling Period*

The model was run for the operating period of 55 years. This modeling period captures the amount of time elapsed from the 1980s, when CCR unit(s) operations started, to 2034, which is the end of the projected active life of BABs.

#### 4.5.3.4 *Talbot Parameters*

POLLUTE uses a Laplace transform to find the solution to the advection-dispersion equation. The numerical inversion of the Laplace transform depends on the Talbot parameters. The model provides default values for the parameters or they can be selected by the user. The default Talbot parameter were used in this demonstration [8].

#### 4.5.3.5 *Boundary Conditions*

POLLUTE allows the user to select between multiple upper and lower boundary conditions. The top boundary condition typically represents the bottom of CCR unit as a potential source. The top boundary can be specified as either zero flux, constant concentration, or finite mass. A constant concentration was assumed as it provides conservative model results since it assumes that the leachate quality will remain constant at the maximum measured values over time.

The lower boundary can be specified as either zero flux, constant concentration, fixed outflow, or infinite thickness. For this model, an infinite thickness lower boundary was used; thus, the model output is a prediction factor of contaminant concentration in groundwater at the interface between the clay with sand layer and the underlying uppermost aquifer.

#### 4.5.3.6 *Darcy Vertical Velocity*

POLLUTE requires a Darcy velocity to be input for the model as a whole. The Darcy velocity was calculated for each basin using a vertical gradient and the vertical hydraulic conductivity of the clay with sand layer. For the BABs, the vertical gradient was calculated using hydrogeologic data from the uppermost aquifer and the normal water elevation as controlled by the outflow structure within the CCR surface impoundment. These parameters were chosen to produce a conservative value for the Darcy velocity. Darcy velocity value of 1.02E-3 m/year was calculated for the BABs as provided in **Appendix M**. The hydraulic conductivity value used for the calculation of Darcy velocity is the average (geometric mean) of historical and current lab testing program vertical hydraulic conductivity data.

#### 4.5.3.7 *Hydrodynamic Dispersion Coefficient*

The vertical coefficient of hydrodynamic dispersion is a required input for each layer within the POLLUTE model. The hydrodynamic dispersion coefficient is calculated using Equation No. 3:

$$\text{Equation No. 3: } D = D^* + av$$

Where:

D = the hydrodynamic dispersion coefficient (m<sup>2</sup>/year);

- $D^*$  = the effective diffusion coefficient ( $m^2/year$ ).
- $a$  = the dispersivity (m);
- $v$  = the groundwater seepage velocity (m/year).

For this demonstration, the coefficient of hydrodynamic dispersion value ( $D$ ) of  $0.19 m^2/year$  was input into the model. This value was based on the effective diffusion coefficient ( $D^*$ ) for chloride ( $0.19 m^2/yr$ ), as calculated by Rowe et al. [9]. The coefficient of chloride was chosen as it is considered to have a high capacity for diffusion compared to other constituents of interest, this it is a conservative constituent to model among the constituents of concern.

The second part of Equation 3,  $(av)$  is related to dispersion. Rowe et al. [9]. Discusses when the seepage velocity ( $1.02E-3 m/year$ ) is low (i.e., clay soils), diffusion will control the parameter hydrodynamic dispersion ( $D$ ) and dispersion is negligible.

#### 4.5.3.8 *Effective Porosity and Density Input*

The average porosity of each model layer was estimated using laboratory data as discussed in Section 2. The model shows good agreement between porosity values and geologic layers, with the overlying clay unit having lower porosities than the underlying clay with sand unit. An average of 46 percent porosity was used for the clay layer, while an average of 42 percent porosity was used for the clay with sand layer.

Based on empirical data provided by Sara (1994) [10], the laboratory porosity data was converted to effective porosities. An effective porosities values of 0.37 and 0.34 for the clay and clay with sand layers were utilized, respectively.

Density values from laboratory testing were also used to determine a suitable model input. The average dry density of  $1,500 kg/m^3$  (94.2 pcf) was assessed from the available data; this value was used in the POLLUTE model.

#### 4.5.3.9 *Adsorption Coefficient and Degradation*

Adsorption and degradation of constituents can play a significant role in the impedance of contaminant migration in the subsurface. Within POLLUTE, the adsorption coefficient simulates the impedance of constituents or sorption of containments in the modeled layers, while degradation simulates the breakdown of contaminants over time. In this model, adsorption and degradation are assumed to be zero, which provides a more conservative model result.

## 4.6 Fate and Transport Analysis Results and Evaluation

### 4.6.1 Fate and Transport Baseline Model Results

The modeling was performed to evaluate predicted groundwater quality based on the hydrogeology of the site. At the BABs, the baseline model calculated a  $PF_t$  of 2.66E-33. With both the  $C_o$  and  $PF_t$  established, the  $PGC_t$  (i.e. predicted concentration) was calculated and compared to the established GWPS for the BABs. As provided in **Table 4-2**, the predicted groundwater quality results, and the 90<sup>th</sup> percentile concentrations from the 2014 EPA study [5] are below the GWPS levels. In addition, the predicted concentrations were added to the highest concentrations that were measured in 2016-2017 groundwater sampling event and compared to the GWPS. The combined results from predicted concentrations and the highest measured concentrations are below the GWPS (see **Tables 4-3**). Therefore, no impacts to groundwater above GWPS are predicted over the duration of BABs' active life.

The driving mechanism for the transport is chemical diffusion, because the advective flow would take more than a thousand years for a water molecule to travel from the bottom of BABs to upper most aquifer. **Appendix M** provides calculations for the time of travel.

The baseline model outputs for the BABs are included in **Appendix N**.

### 4.6.2 Sensitivity Analysis

Many of the model inputs are specific to the site. Given the potential for sampling bias, uncertainty, and natural variation, a sensitivity analysis was conducted to evaluate the impact on the variation of the model inputs. The analysis focused on changes to the model output, or  $PF_t$ , given a variation to a single model input as discussed in the following sections. A summary of the sensitivity analyses model input values is provided in **Table 4-4**. The resulting  $PF_t$  from each sensitivity analysis was compared to a threshold prediction value,  $PF_{\text{threshold}}$ . The  $PF_{\text{threshold}}$  value represents the  $PF_t$  at which impacts to groundwater are predicted for Appendix IV COCs at the top of the uppermost aquifer under the CCR unit; the threshold value is 0.2 for the northern BAB and 0.6 for the southern BAB.  $PF_{\text{threshold}}$  is calculated using the Equation No. 4:

$$\text{Equation No. 4: } PF_{\text{threshold}} = \min \left\{ \frac{GWPS_1}{C_1}, \frac{GWPS_2}{C_2}, \dots, \frac{GWPS_i}{C_i}, \dots, \frac{GWPS_n}{C_n} \right\}$$

Where:

$PF_{\text{threshold}}$  = Threshold Prediction Factor

$GWPS_i$  = Groundwater Protection Standard for Constituent 'i'

$C_i$  = Maximum porewater concentration of the COC 'i'

#### 4.6.2.1 *Darcy Velocity*

A sensitivity analysis was completed to evaluate the impact of Darcy velocity changes. A Darcy velocity of 2.03E-3 m/year was selected as the value to use for this analysis. This value is double the baseline value calculated during this demonstration and thus serves as a suitable value for input to the sensitivity analysis.

#### 4.6.2.2 *Coefficient of Hydrodynamic Dispersion*

Model sensitivity to the coefficient of hydrodynamic dispersion was evaluated by increasing and decreasing the input value by 25%. The initial input value was derived from laboratory testing (Rowe et al., 2004) [9], and thus a 25% increase and decrease is considered a satisfactory variation for sensitivity analysis.

#### 4.6.2.3 *Porosity and Effective Porosity*

Model sensitivity to the porosity and effective porosity was evaluated by increasing and decreasing the input value by the minimum and maximum range of values calculated from the laboratory results.

#### 4.6.2.4 *Layer Thickness*

The isopach maps (**Appendix M**) were used to calculate the maximum and minimum thickness for the clay and clay with sand layers. Using those values as inputs, four additional models were run for each CCR unit to evaluate model sensitivities to layer thickness; in each model only one variable was changed.

#### 4.6.2.5 *Modeling Period*

The modeling period used was 55 years (the “baseline”). To further evaluate the impact of modeling runtime on the resultant PF<sub>t</sub>, one model was run with a modeling period of 85 years, to capture the post-closure care time period, though DTE intends to close the BABs by removal.

#### 4.6.2.6 *Sensitivity Results*

Additional fate and transport model runs were completed to evaluate model sensitivities to changing model inputs. As shown in **Table 4-5** using more conservative model input parameters resulted in PF<sub>t</sub> values ranging from 6.23E-38 to 1.30E-26. This demonstrates that the BABs will not impact groundwater quality assuming conditions more conservative than the baseline scenario. The sensitivity modeling results are presented in **Table 4-5** whereas the model outputs are included in **Appendix N**.

### 4.6.3 Reliability of Computer Model

The computer-based transport model used for this analysis is based on rigorous and proven analytical solutions to the advection-dispersion equation for layered deposits. These equations were derived with the intent of modeling the physical and chemical transport of contaminants from waste impoundments. Widespread use, comprehensive documentation, and abundant publications (Talbot, 1979 [8]; Rowe, 1987 [11]; Rowe and Booker, 1987 [12]; Rowe, 1988 [7]; and Rowe and Booker, 1989 [13]) lend to the versatility of this modeling approach for assessing groundwater impacts. The outputs obtained from models conducted in POLLUTE can be compared to those obtained using other approaches to solving the advection-dispersion equation.

### 4.6.4 Degree of Conservativeness in Model Results

Input parameters for the baseline models were based on site-specific data whenever possible. When not possible, input values were derived from an understanding of the site and relevant peer-reviewed literature. If a high degree of uncertainty was present, conservative input values were selected. A summary of the various conservative assumptions is listed below:

- The maximum measured leachate (i.e., porewater) concentration for each constituent was used for the fate and transport model prediction table;
- Constant leachate concentration or a constant mass was used for the entire modeling period. A specific mass could have been assumed for modeling purposes which would have resulted in decrease leachate concentrations over time but to be conservative the model assumed constant leachate concentration over time;
- Adsorption can significantly reduce the concentrations of metal constituents as they move through soils, especially clays which would retard or slow down migration. To be conservative, the model assumed no adsorption would occur over time;
- Degradation of leachate (input values) through either biologic or chemical process was assumed not to occur during the modelling period. By assuming no degradation, the model overestimates the predicted groundwater quality over time; and
- The CCR Rule requires compliance at the waste boundary. The analysis only considers vertical flow from the bottom of FAB to the top of the uppermost aquifer; the analysis does not consider a 2-D flow towards the waste boundary, which would further lower the predicted concentration levels for COCs.

## 5. SUMMARY

This Preliminary ALD has been prepared to assess if the BABs CCR unit meets the ALD requirements per the CCR Rule. The data included comprehensive field and laboratory investigation data collected from the 1970s to 2020. The 2020 field and laboratory investigation studies were conducted specifically to augment data gaps and to address the CCR Rule requirements. The data were integrated into an EVS model to create a comprehensive CSM to understand the BABs lithology beneath the CCR unit and as a basis for the Fate and Transport analysis. The EVS model was relatively consistent with historic representations of the geology associated with the BABs CCR unit.

Site-specific water was collected from BABs and DB and tested to assess which one of the CCR units had the more aggressive water. Water from DB was deemed to be more aggressive and used for compatibility testing to estimate the impacts on the hydraulic conductivity of soil samples. The testing program is still underway. The most current results from the testing have been used in this ALD.

A comprehensive subsurface stratigraphy model was created using the augmented data set and processing it through the EVS. Following, Fate and Transport analysis was conducted to assess whether there is a reasonable probability that water from BABs may result from releases to groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary.

The Fate and Transport analysis was conducted for the operating time period of 55 years (“baseline”), which captures the amount of time elapsed from the 1980s, when CCR unit operations started, to 2034, which is the end of the projected active life of BABs.

The analysis considered different contaminant transport mechanisms including, advection, dispersion, and diffusion. The analysis indicates that advective flow would take more than a thousand years for a water molecule to travel from the bottom of BABs to upper most aquifer. Therefore, the analysis results indicate that, due to the low permeability nature of the in-situ unconsolidated materials, chemical diffusion is the dominant transport mechanism as opposed to advection or seepage velocity. Consequently, the current hydraulic conductivity testing described in Section 3 is sufficient to characterize hydraulic conductivity and demonstrate the performance of the alternate liner system as it relates to advection or seepage flow. It is highly unlikely that running the samples until they achieve termination criteria would change the outcome of this study, and therefore, the tests do not need to extend until March 2022.

The Fate and Transport analysis was augmented with a sensitivity analysis to account for sampling bias, uncertainty, and natural variation in site-specific inputs. Predicted groundwater concentrations for both the baseline and sensitivity analyses are below GWPS. The analysis results

show that there is no reasonable probability that water from BABs will cause releases to groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary over the projected active life of the CCR unit.

6. CERTIFICATION

**CCR Unit:** DTE Electric Company; Belle River Power Plant, Bottom Ash Basins (BABs)

I, Omer Bozok, being a Registered Professional Engineer in good standing in the State of Michigan, do hereby certify in accordance with the CCR Rule, to the best of my knowledge, information, and belief, that the information contained in this plan has been prepared in accordance with the accepted practice of engineering and that the BABs meets the requirements of the Alternative Liner Demonstration per the CCR Rule.

Omer Bozok

**Table 3-3 – Summary of pH Results**

Sample ID	Parameter	pH Inflow	pH Outflow	Is pH of outflow within termination boundaries?
B1-ST-1 (7-9')	Min	8.2	8.1	Yes
	Max	8.6	8.6	
	Average	8.4	8.4	
B2-ST-1 (1-3')	Min	8.0	7.9	Yes
	Max	8.8	8.5	
	Average	8.4	8.2	
B2-ST-4 (47-49')	Min	8.0	8.0	Yes
	Max	8.6	8.4	
	Average	8.3	8.2	
B3-ST-5 (77-79')	Min	8.1	7.8	Yes
	Max	8.8	8.6	
	Average	8.3	8.1	
B4-ST-3 (47-49')	Min	7.7	7.8	Yes
	Max	8.7	8.7	
	Average	8.2	8.1	
B5-ST-5 (87-89')	Min	7.9	8.0	Yes
	Max	8.6	8.5	
	Average	8.4	8.2	

**Table 3-4 – Summary of Electrical Conductivity Results**

Sample ID	Parameter	EC Inflow (µs/cm)	EC Outflow (µs/cm)	Is EC of outflow within termination boundaries?	Approximate Projected Termination Date
B1-ST-1 (7-9')	Min	656	1230	No	November 12, 2021
	Max	660	1614		
	Average	657	1418		
B2-ST-1 (1-3')	Min	560	1764	No	December 23, 2021
	Max	782	3050		
	Average	645	2146		
B2-ST-4 (47-49')	Min	523	933	No	October 12, 2021
	Max	666	1313		
	Average	609	1087		
B3-ST-5 (77-79')	Min	611	816	No	September 12, 2021
	Max	735	1118		
	Average	680	946		
B4-ST-3 (47-49')	Min	518	597	No	September 1, 2021
	Max	730	930		
	Average	625	778		
B5-ST-5 (87-89')	Min	598	1040	No	September 5, 2021
	Max	760	2010		
	Average	678	1341		

**Table 3-5 – Sample Condition as it Relates to Termination Criteria**

Sample ID	Termination Criterion Reached				
	Pore Volumes Passed, PV	pH	Electrical Conductivity, EC	Approximate Projected Termination Date	Date Based On
B1-ST-1 (7-9')	No	Yes	No	March 23, 2022	PV
B2-ST-1 (1-3')	No	Yes	No	December 23, 2021	EC
B2-ST-4 (47-49')	No	Yes	No	October 12, 2021	EC
B3-ST-5 (77-79')	Yes	Yes	No	September 12, 2021	EC
B4-ST-3 (47-49')	Yes	Yes	No	September 1, 2021	EC
B5-ST-5 (87-89')	No	Yes	No	September 5, 2021	EC

**Table 4-4 – Sensitivity Analysis Model Inputs**

	Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis	Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis
<i>Layer Properties</i>	Thickness (m)	Max Thickness (m)	Min Thickness (m)	Dv (m/yr)	Dv (m/yr)	CoHD	CoHD +25%	CoHD -25%	Total Porosity	Max Porosity	Min Porosity	Effective Porosity	Eff. Porosity Max	Eff. Porosity Min	Modeling Period (years)	Modeling Period (years)
Clay	12.01	13.99	11.03	1.02E-03	2.03E-03	0.019	0.024	0.014	0.46	0.56	0.34	0.37	0.45	0.28	55	85
Clay with Sand	19.29	23.62	15.18	1.02E-03	2.03E-03	0.019	0.024	0.014	0.42	0.55	0.24	0.34	0.45	0.20	55	85

Dv = Vertical Darcy Velocity

CoHD = Coefficient of Hydrodynamic Dispersion

**Table 4-5 – Sensitivity Analysis Results Prediction Factors**

<b>Bottom Ash Basins Sensitivity Analysis</b>			
<b>Model Name</b>	<b>Description</b>	<b>Prediction Factor</b>	<b>Pass?*</b>
BAB_Baseline	Baseline model for the Bottom Ash Basins.	2.66E-33	YES
BAB_ExtendedRun	Model runtime was extended from 55 years to 85 years.	1.30E-26	YES
BAB_Darcy	Darcy velocity was doubled.	2.52E-32	YES
BAB_CoHD_High	Coefficient of Hydrodynamic Dispersion was increased by 25%.	1.53E-30	YES
BAB_CoHD_Low	Coefficient of Hydrodynamic Dispersion was decreased by 25%.	6.23E-38	YES
BAB_ClayPoro_High	Used the highest effective porosity in clay interval; derived from laboratory data in project database.	2.50E-33	YES
BAB_ClayPoro_Low	Used the lowest effective porosity in clay interval; derived from laboratory data in project database.	3.08E-33	YES
BAB_SandPoro_High	Used the highest effective porosity in clay with sand interval; derived from laboratory data in project database.	1.67E-33	YES
BAB_SandPoro_Low	Used the lowest effective porosity in clay with sand interval; derived from laboratory data in project database.	1.06E-32	YES
BAB_ClayThick	Used thickest clay interval seen in boring/well; derived from project database.	3.60E-35	YES
BAB_ClayThin	Used thinnest clay interval seen in boring/well; derived from project database.	1.92E-32	YES
BAB_SandThick	Used thickest clay with sand interval seen in boring/well; derived from project database.	1.48E-37	YES
BAB_SandThin	Used thinnest clay with sand interval seen in boring/well; derived from project database.	1.36E-29	YES
* Indicates value less than $PF_{\text{threshold}}$ , as discussed in Section 4.6.2.

MW-16-01b	3/1/2016	Falling Head	3.58E-04	1.015
		Rising Head	2.72E-04	0.770
		<b>Average</b>	<b>3.15E-04</b>	<b>0.892</b>
MW-16-04	3/1/2016	Falling Head	7.93E-05	0.225
		Rising Head	4.11E-05	0.116
		<b>Average</b>	<b>6.02E-05</b>	<b>0.171</b>
MW-16-05	3/1/2016	Falling Head	4.26E-05	0.121
		Rising Head	2.13E-05	0.060
		<b>Average</b>	<b>3.19E-05</b>	<b>0.090</b>
MW-16-07	3/1/2016	Falling Head	1.24E-04	0.350
		Rising Head	7.21E-05	0.204
		<b>Average</b>	<b>9.79E-05</b>	<b>0.277</b>
<b>Minimum</b>			<b>3.19E-05</b>	<b>9.05E-02</b>
<b>Maximum</b>			<b>3.15E-04</b>	<b>8.92E-01</b>
<b>Geometric Mean</b>			<b>8.77E-05</b>	<b>0.249</b>

**Conversion:**

$$\frac{1 \text{ cm}}{1 \text{ sec}} \times \frac{86,400 \text{ sec}}{1 \text{ day}} \times \frac{1 \text{ ft}}{30.48 \text{ cm}} = 2.83\text{E}+03 \frac{\text{ft}}{\text{day}}$$

**Notes:**

Slug test results calculated using the Bower-Rice (1976) Solution.

MW-16-01 FALLING HEAD SLUG TEST

Data Set: P:\...\\MW-16-01\_IN.aqt

Date: 05/22/17

Time: 13:38:07

PROJECT INFORMATION

Company: TRC Environmental Corporation

Client: DTE EC BRPP CCR

Project: 231828.0003.0000

Location: China Township, MI

Test Well: MW-16-01

Test Date: 4/13/16

AQUIFER DATA

Saturated Thickness: 52. ft

Anisotropy Ratio ( $K_z/K_r$ ): 1.

WELL DATA (MW-16-01)

Initial Displacement: 0.835 ft

Static Water Column Height: 84.12 ft

Total Well Penetration Depth: 84.12 ft

Screen Length: 5. ft

Casing Radius: 0.08333 ft

Well Radius: 0.08333 ft

SOLUTION

Aquifer Model: Confined

Solution Method: Bower-Rice

$K = 0.0003581$  cm/sec

$y_0 = 0.7491$  ft

**DESCRIPTION**

Cinders, fill  
Sandy topsoil  
Soft, brown & gray, silty Clay (CH)  
trace fine sand, high plasticity  
Stiff, brown, some fine sand

Very soft to soft, gray, silty Clay (CH-CL)

Firm, gray, sandy clay layer

Gray, silty Clay (CL) medium plasticity, 20% fine to coarse sand

Stiff, dark, gray clayey sand (SC)

Firm to stiff, gray, silty clay (CL), silt lenses  
Hard, some fine sand

Compact, gray, fine sand (SP)

silty fine sand (SM) 15% nonplastic fines

Compact, gray, very fine to coarse sand (SW)

Silty sand (SM) 15% nonplastic fines

Bottom of hole - Elevation - 451.4  
- Depth - 135.0 ft

This hole stopped at 135.0 ft. due to gas.

With casing at 110.0' no gas. Casing pulled to 57.0'. No gas. Pulled to 50.0', gas bubbling in hole. Capped hole and left for 48 hours. After 48 hours no gas (pocket only)

2-8-74 No gas  
2-11-74 Gas  
2-11-74 Pulled to 50.0', capped  
2-11-74 1400 hours removed cap (no gas)

82.5' - 107.0' used Gel to keep open

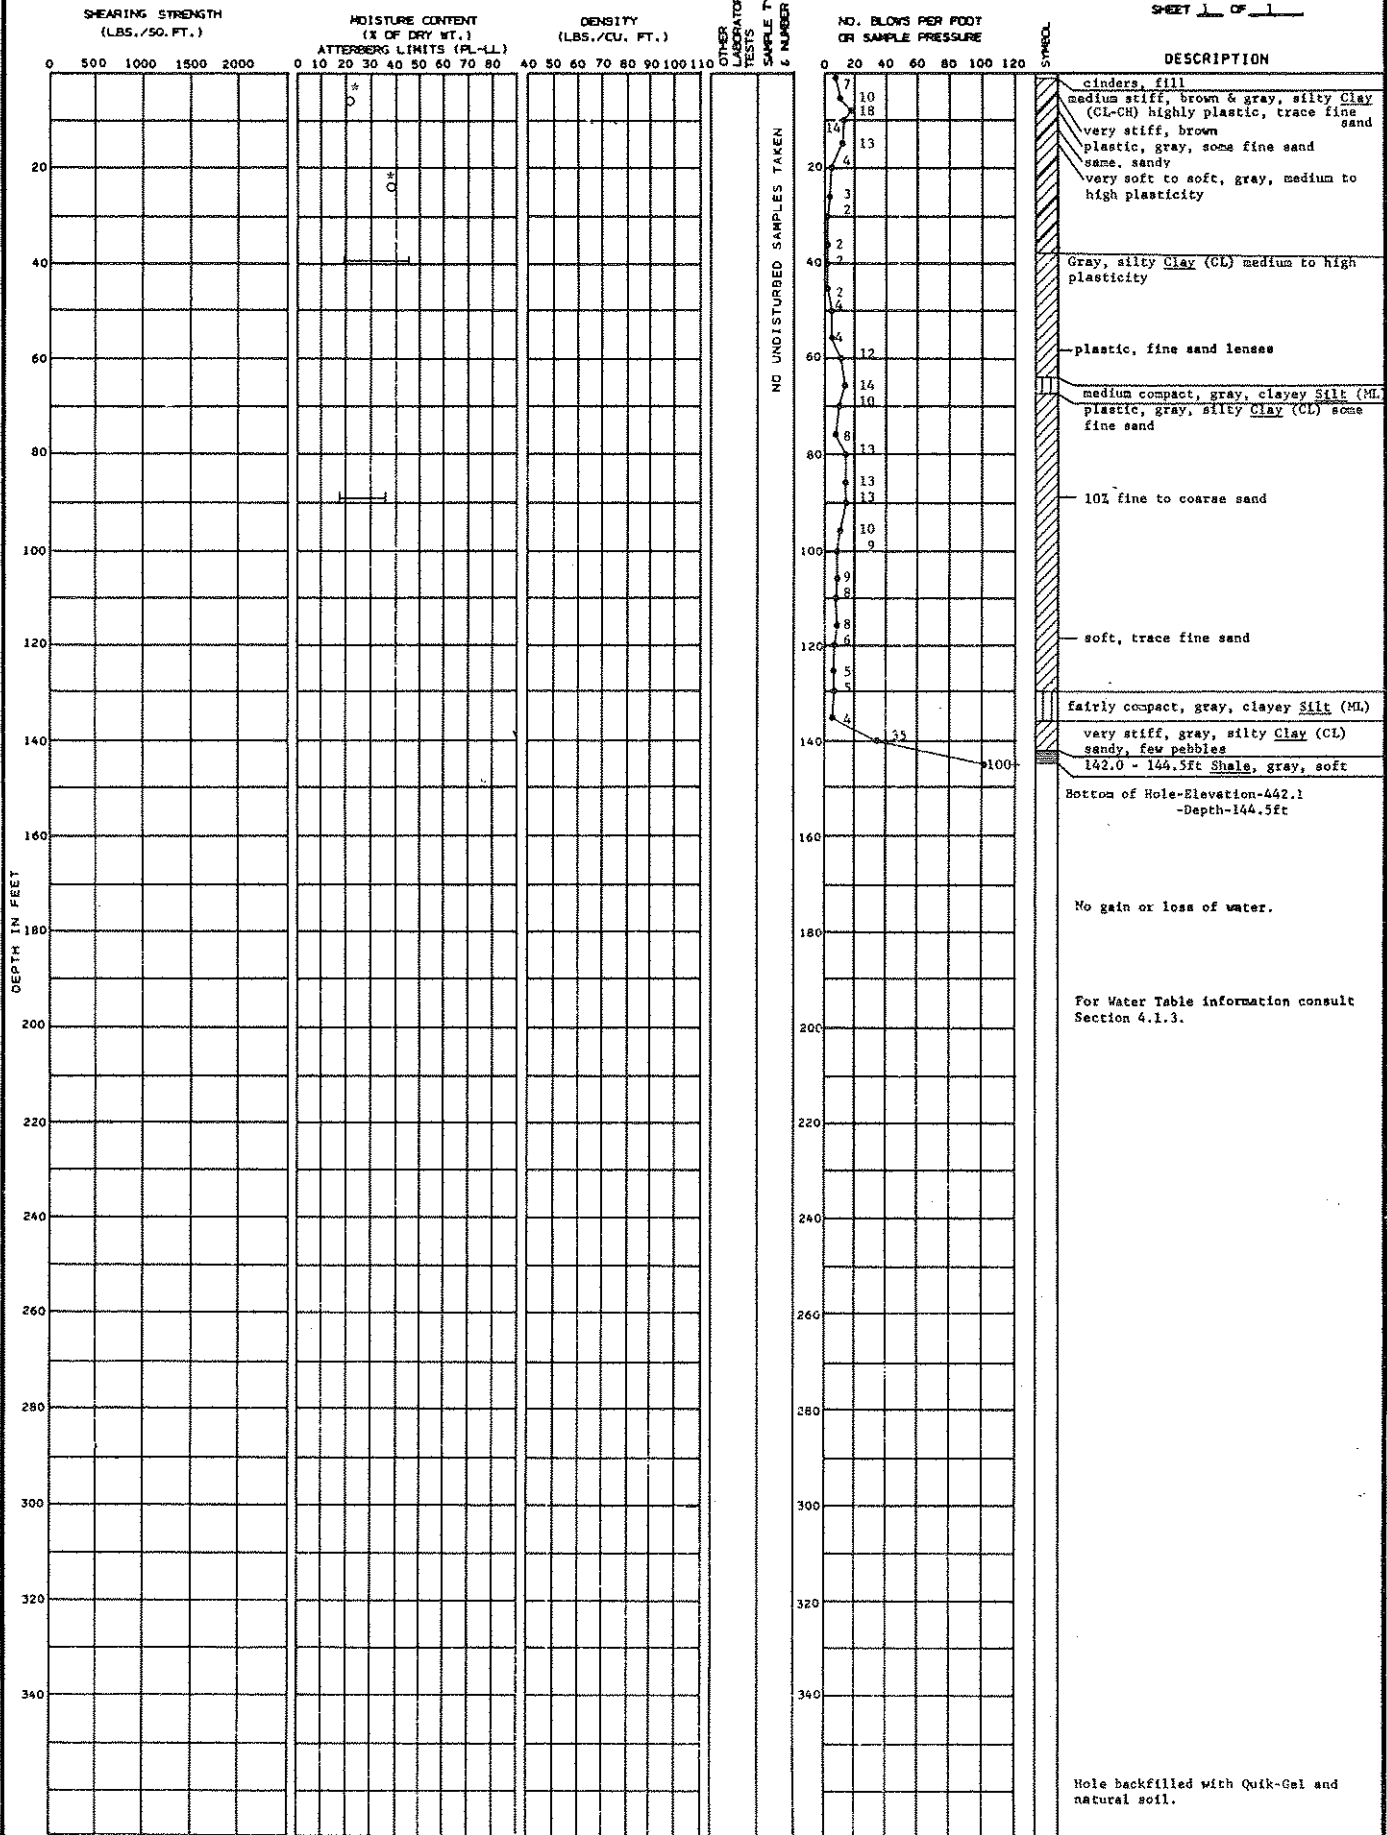

For Water Table information consult Section 4.1.3.

DESCRIPTION

0-10.0' Water

10.0-10.3' Sandy Clay, dark gray to black, very soft, wet, trace fine to coarse gravel (CL)

10.3-43.5' Clay, gray-brown, med. stiff, high plasticity, moist to wet, trace silt (CH)

18.0-43.5' Very soft

43.5-122.0' Silty Clay, med. gray, med. stiff, med. plasticity, moist, trace to little sand, trace fine gravel (CL)

93.5-113.5' Very stiff, trace sand

113.5-122.0' Med. stiff, trace silt, trace sand

122.0-127.0' Silt, light gray, very dense, dry, with fine sand (ML)

127.0' Top of Rock

127.0-144.0' Shale, med. gray, soft, weathered

131.7-144.0' Moderately hard with soft clay interbeds

139.0-144.0' Occasional soft clay layers

Bottom of Hole: Depth 144.0'  
Elevation 433.5

Hole grouted from 127.0' to ground surface.

SUBJECT: Soil Testing  
Hopper Investigation  
Belle River Coal Handling  
Detroit Edison Company  
Technical Specification, 10539-3-C-13  
REFERENCE: Purchase Order No. AA2184

Dear Sir:

Enclosed herewith is the summary of laboratory testing conducted on soil samples received from the subject site, as authorized by the referenced purchase order. The laboratory testing was performed in accordance with your technical specification 10539-3-C-13 and included the following tests:

	<u>Pages</u>
30 Visual Classification and In-Situ Moistures	B-1, B-2, B-9
10 Atterberg Limits	B-3, B-4, B-5
30 Unconfined Compression	B-6 through B-28
2 In-Situ Moisture and Density	B-6, B-8
5 Mechanical Analysis	B-29, B-30

We appreciate the opportunity of serving you and trust that this work has been performed to your satisfaction.

Very truly yours,

U. W. STOLL AND ASSOCIATES

In-Kuin Kim, P.E.

# LAST PAGE

**Test Applicability and Limitations:**

- The results are applicable only for the materials received at the laboratory and tested which may or may not be representative of the materials at the site.

**Storage Policy:**

- Uncontaminated Material: All samples (or what is left) will be archived for a period of 3 months from the date received. Thereafter the samples will be discarded unless a written request for extended storage is received. A rate of \$1.00 per sample per day will be applied after the initial 3 month storage period.

- Contaminated Material: All samples (or what is left) will be archived for a period of 3 months from the date received. Thereafter, the samples will be returned to the project manager or his/her designated receiver unless a written request for extended storage is received. A rate of \$1.30 per sample per day will be applied after the initial 3 months storage.

Re: **DTE- Belle River (GLP-8017)**

Work Order: **20121752**

Dear Michael,

ALS Environmental received 3 samples on 18-Dec-2020 10:00 AM for the analyses presented in the following report.

The analytical data provided relates directly to the samples received by ALS Environmental - Holland and for only the analyses requested.

Sample results are compliant with industry accepted practices and Quality Control results achieved laboratory specifications. Any exceptions are noted in the Case Narrative, or noted with qualifiers in the report or QC batch information. Should this laboratory report need to be reproduced, it should be reproduced in full unless written approval has been obtained from ALS Environmental. Samples will be disposed in 30 days unless storage arrangements are made.

The total number of pages in this report is 21.

If you have any questions regarding this report, please feel free to contact me:

ADDRESS: 3352 128th Avenue, Holland, MI, USA  
PHONE: +1 (616) 399-6070 FAX: +1 (616) 399-6185

Sincerely,

A handwritten signature in black ink, appearing to read "Chad Whelton", is written over a light blue horizontal line.

Electronically approved by: Chad Whelton

Chad Whelton  
Project Manager

---

**Case Narrative**

Samples for the above noted Work Order were received on 12/18/2020. The attached "Sample Receipt Checklist" documents the status of custody seals, container integrity, preservation, and temperature compliance.

Samples were analyzed according to the analytical methodology previously transmitted in the "Work Order Acknowledgement". Methodologies are also documented in the "Analytical Result" section for each sample. Quality control results are listed in the "QC Report" section. Sample association for the reported quality control is located at the end of each batch summary. If applicable, results are appropriately qualified in the Analytical Result and QC Report sections. The "Qualifiers" section documents the various qualifiers, units, and acronyms utilized in reporting. A copy of the laboratory's scope of accreditation is available upon request.

With the following exceptions, all sample analyses achieved analytical criteria.

**Metals:**

No other deviations or anomalies were noted.

**Wet Chemistry:**

Batch R306912, Method SW9040C, Sample BAB-E (20121752-01B): pH is considered a "field test" and, as such, the recommended sample holding time expired prior to sample receipt.

Batch R306912, Method SW9040C, Sample BAB-W (20121752-02B): pH is considered a "field test" and, as such, the recommended sample holding time expired prior to sample receipt.

Batch R306912, Method SW9040C, Sample DB (20121752-03B): pH is considered a "field test" and, as such, the recommended sample holding time expired prior to sample receipt.

Batch R307145, Method SW9056A, Sample 20121752-03B MSD: The MSD recovery was outside of the control limit for Sulfate; however, the result in the parent sample is greater than 4x the spike amount. No qualification is required.

<u>Qualifier</u>	<u>Description</u>
*	Value exceeds Regulatory Limit
**	Estimated Value
a	Analyte is non-accredited
B	Analyte detected in the associated Method Blank above the Reporting Limit
E	Value above quantitation range
H	Analyzed outside of Holding Time
Hr	BOD/CBOD - Sample was reset outside Hold Time, value should be considered estimated.
J	Analyte is present at an estimated concentration between the MDL and Report Limit
ND	Not Detected at the Reporting Limit
O	Sample amount is > 4 times amount spiked
P	Dual Column results percent difference > 40%
R	RPD above laboratory control limit
S	Spike Recovery outside laboratory control limits
U	Analyzed but not detected above the MDL
X	Analyte was detected in the Method Blank between the MDL and Reporting Limit, sample results may exhibit background or reagent contamination at the observed level.

<u>Acronym</u>	<u>Description</u>
DUP	Method Duplicate
LCS	Laboratory Control Sample
LCSD	Laboratory Control Sample Duplicate
LOD	Limit of Detection (see MDL)
LOQ	Limit of Quantitation (see PQL)
MBLK	Method Blank
MDL	Method Detection Limit
MS	Matrix Spike
MSD	Matrix Spike Duplicate
PQL	Practical Quantitation Limit
RPD	Relative Percent Difference
TDL	Target Detection Limit
TNTC	Too Numerous To Count
A	APHA Standard Methods
D	ASTM
E	EPA
SW	SW-846 Update III

<u>Units Reported</u>	<u>Description</u>
°C	Degrees Celcius
mg/L	Milligrams per Liter
s.u.	Standard Units

Re: ALS Workorder: 2012397  
Project Name: DTE - Belle River  
Project Number: GLP-8017

Dear Mr. Coram:

Three water samples were received from Geosyntec Consultants, on 12/18/2020. The samples were scheduled for the following analyses:

Radium-226

Radium-228

The results for these analyses are contained in the enclosed reports.

The data contained in the following report have been reviewed and approved by the personnel listed below. In addition, ALS certifies that the analyses reported herein are true, complete and correct within the limits of the methods employed. Should this laboratory report need to be reproduced, it should be reproduced in full unless written approval has been obtained from ALS Environmental.

Thank you for your confidence in ALS Environmental. Should you have any questions, please call.

Sincerely,

ALS Environmental  
Julie Ellingson  
Project Manager

Accreditations: ALS Environmental – Fort Collins is accredited by the following accreditation bodies for various testing scopes in accordance with requirements of each accreditation body. All testing is performed under the laboratory management system, which is maintained to meet these requirement and regulations. Please contact the laboratory or accreditation body for the current scope testing parameters.

ALS Environmental – Fort Collins	
Accreditation Body	License or Certification Number

40 CFR Part 136: All analyses for Clean Water Act samples are analyzed using the 40 CFR Part 136 specified method and include all the QC requirements.

## 2012397

### **Radium-228:**

The samples were analyzed for the presence of  $^{228}\text{Ra}$  by low background gas flow proportional counting of  $^{228}\text{Ac}$ , which is the ingrown progeny of  $^{228}\text{Ra}$ , according to the current revision of SOP 724.

All remaining acceptance criteria were met.

### **Radium-226:**

The samples were prepared and analyzed according to the current revision of SOP 783.

Sample 2012397-2 has a calculated yield as determined by ICP-AES above the 110% control limit at 132%. It is believed that there was native barium present in the sediment portion of the sample that was unaccounted for in the initial ICP aliquot. The result has been calculated conservatively, assuming a quantitative yield of 100%. This sample is identified with a "Y2" flag in the final reports, and the results are submitted without further qualification.

All remaining acceptance criteria were met.

**CONDITION OF SAMPLE UPON RECEIPT FORM**

Client Name/ID:

Geosyntec MI

Workorder No:

2012397

Project Manager:

Initials:

RGA

Date: 12/18/2020

1. Are airbills / shipping documents present and/or removable?	<input type="checkbox"/> Drop Off	<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO
2. Are custody seals on <b>shipping</b> containers intact?	<input type="checkbox"/> NONE	<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO*
3. Are custody seals on <b>sample</b> containers intact?	<input checked="" type="checkbox"/> NONE	<input type="checkbox"/> YES	<input type="checkbox"/> NO*
4. Is there a COC (chain-of-custody) present?		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO*
5. Is the COC in agreement with samples received? (IDs, dates, times, # of samples, # of containers, matrix, requested analyses, etc.)		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO*
6. Are short-hold samples present?		<input type="checkbox"/> YES	<input checked="" type="checkbox"/> NO
7. Are all samples within holding times for the requested analyses?		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO*
8. Were all sample containers received intact? (not broken or leaking)		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO*
9. Is there sufficient sample for the requested analyses?		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO*
10. Are samples in proper containers for requested analyses? (form 250, <i>Sample Handling Guidelines</i> )		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO*
11. Are all aqueous samples preserved correctly, if required?	<input type="checkbox"/> N/A	<input type="checkbox"/> YES	<input checked="" type="checkbox"/> NO*
12. Were unpreserved samples pH checked, if required?	<input checked="" type="checkbox"/> N/A	<input type="checkbox"/> YES	<input type="checkbox"/> NO
13. Are all samples requiring no headspace (VOC, GRO, RSK/MEE, radon) free of bubbles > 6 mm in diameter?	<input checked="" type="checkbox"/> N/A	<input type="checkbox"/> YES	<input type="checkbox"/> NO
14. Were the samples shipped on ice?		<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO
15. Were cooler temperatures measured at 0.1 - 6.0°C?	IR gun used: <input type="checkbox"/> #3 <input checked="" type="checkbox"/> #5	<input type="checkbox"/> Rad Only	<input checked="" type="checkbox"/> YES <input type="checkbox"/> NO

Cooler #: 1

Temperature (°C): 3.2

# of custody seals on cooler: 1

External mR/hr reading: 12

Background mR/hr reading: 9

Were external mR/hr readings ≤ two times background and within DOT acceptance criteria? (If no, see Form 008)

N/A  YES  NO

\* Please provide details below for 'NO' responses in gray boxes above - for 2 thru 5 & 7 thru 12, notify PM & continue w/ login.

11) Sample 2012397-1-2 had a pH of 4, 0.5mL of HNO3 was added to achieve a pH<2

All client bottle ID's vs ALS lab ID's double-checked by: RGA

If applicable, was the client contacted?  YES  N/A

Analyses	Result	Qual	Report Limit	Units	Dilution Factor	Date Analyzed
----------	--------	------	--------------	-------	-----------------	---------------

**Explanation of Qualifiers**

**Radiochemistry:**

- "Report Limit" is the MDC
- U or ND - Result is less than the sample specific MDC.
- Y1 - Chemical Yield is in control at 100-110%. Quantitative yield is assumed.
- Y2 - Chemical Yield outside default limits.
- W - DER is greater than Warning Limit of 1.42
- \* - Aliquot Basis is 'As Received' while the Report Basis is 'Dry Weight'.
- # - Aliquot Basis is 'Dry Weight' while the Report Basis is 'As Received'.
- G - Sample density differs by more than 15% of LCS density.
- D - DER is greater than Control Limit
- M - Requested MDC not met.
- M3 - The requested MDC was not met, but the reported activity is greater than the reported MDC.
- L - LCS Recovery below lower control limit.
- H - LCS Recovery above upper control limit.
- P - LCS, Matrix Spike Recovery within control limits.
- N - Matrix Spike Recovery outside control limits
- NC - Not Calculated for duplicate results less than 5 times MDC
- B - Analyte concentration greater than MDC.
- B3 - Analyte concentration greater than MDC but less than Requested MDC.

**Inorganics:**

- B - Result is less than the requested reporting limit but greater than the instrument method detection limit (MDL).
- U or ND - Indicates that the compound was analyzed for but not detected.
- E - The reported value is estimated because of the presence of interference. An explanatory note may be included in the narrative.
- M - Duplicate injection precision was not met.
- N - Spiked sample recovery not within control limits. A post spike is analyzed for all ICP analyses when the matrix spike and or spike duplicate fail and the native sample concentration is less than four times the spike added concentration.
- Z - Spiked recovery not within control limits. An explanatory note may be included in the narrative.
- \* - Duplicate analysis (relative percent difference) not within control limits.
- S - SAR value is estimated as one or more analytes used in the calculation were not detected above the detection limit.

**Organics:**

- U or ND - Indicates that the compound was analyzed for but not detected.
- B - Analyte is detected in the associated method blank as well as in the sample. It indicates probable blank contamination and warns the data user.
- E - Analyte concentration exceeds the upper level of the calibration range.
- J - Estimated value. The result is less than the reporting limit but greater than the instrument method detection limit (MDL).
- A - A tentatively identified compound is a suspected aldol-condensation product.
- X - The analyte was diluted below an accurate quantitation level.
- \* - The spike recovery is equal to or outside the control criteria used.
- + - The relative percent difference (RPD) equals or exceeds the control criteria.
- G - A pattern resembling gasoline was detected in this sample.
- D - A pattern resembling diesel was detected in this sample.
- M - A pattern resembling motor oil was detected in this sample.
- C - A pattern resembling crude oil was detected in this sample.
- 4 - A pattern resembling JP-4 was detected in this sample.
- 5 - A pattern resembling JP-5 was detected in this sample.
- H - Indicates that the fuel pattern was in the heavier end of the retention time window for the analyte of interest.
- L - Indicates that the fuel pattern was in the lighter end of the retention time window for the analyte of interest.
- Z - This flag indicates that a significant fraction of the reported result did not resemble the patterns of any of the following petroleum hydrocarbon products:
  - gasoline
  - JP-8
  - diesel
  - mineral spirits
  - motor oil
  - Stoddard solvent
  - bunker C

## Technical Memorandum

---

**Date:** November 24, 2021

**To:** Chris Scieszka, DTE Electric Company

**From:** Vince Buening, TRC  
Sarah Holmstrom, TRC  
Kristin Lowery, TRC

**Project No.:** 413591.0003.0000 Phase 1 Task 1

**Subject:** Groundwater Protection Standard Calculation – DTE Electric Company, Belle River Power Plant Bottom Ash Basins

---

DTE Electric Company (DTE Electric) is pursuing an Alternate Liner Demonstration (ALD) for the Belle River Power Plant (BRPP) Bottom Ash Basins (BABs) coal combustion residual (CCR) unit. On November 12, 2020, the U.S. EPA published the Part B: Alternate Demonstration for Unlined Surface Impoundments amendments to the CCR Rule<sup>1</sup> (“Part B”) that allows a facility to prepare demonstration to request approval to operate an existing CCR surface impoundment with an alternate liner. Although the BRPP BABs remain in detection monitoring, per § 257.71(d)(1)(ii)(C)(2), the ALD must demonstrate that, for each Appendix IV constituent, there is no reasonable probability that the peak groundwater concentration that may result from releases that occur over the active life of the CCR surface impoundment will exceed the groundwater protection standard (GWPS) at the waste boundary.

GWPSs are set as either specific regulatory standards identified in the CCR Rule or background groundwater concentrations, whichever is higher, for the Appendix IV constituents. Per the CCR Rule §257.95(h)<sup>2</sup>, the EPA maximum contaminant levels (MCLs) will be the GWPSs for those constituents that have established MCLs. For Appendix IV constituents that do not have established MCLs, the GWPSs are based upon the EPA Regional Screening Levels (RSLs). For constituents that have statistically derived background levels higher than the MCL and/or RSL, the GWPS becomes equal to the background level.

This memorandum presents the background statistical limits and GWPS derived for the Appendix IV parameters for the BRPP BABs CCR unit using the aforementioned approach pursuant to §257.95(h). Per 40 CFR §257.94, a minimum of eight rounds of background sampling for the Appendix IV constituents were completed at the BRPP BABs from August 2016 through September 2017, as part of

---

<sup>1</sup> On April 17, 2015, the U.S. EPA issued the Final Rule: Disposal of CCR from Electric Utilities (CCR Rule), 40 CFR 257, Subpart D, to regulate the disposal of CCR materials generated at coal-fired units.

<sup>2</sup> As amended per Phase One, Part One of the CCR Rule (83 FR 36435).

## Technical Memorandum

initiating the detection monitoring program. Since fluoride is in both the Appendix III and Appendix IV constituent lists, additional fluoride data were collected under the detection monitoring program subsequent to September 2017 and were also used in the development of the GWPS. All of the Appendix IV data used in this analysis (August 2016 through December 2020) and details on how the data were collected are included in the annual reports prepared in accordance with the CCR Rule through January 2021.

The background data for the BRPP BABs were evaluated in accordance with the *Groundwater Statistical Evaluation Plan* (Stats Plan) (TRC, October 2017). Per the Stats Plan, the BRPP BABs CCR unit uses an intra-well statistical approach. For intra-well methods, the background data set is comprised of the historical data established at each individual monitoring well, which accounts for natural spatial variability that occurs in background encountered across the site. Background data were evaluated utilizing ChemStat™ statistical software. ChemStat™ is a software tool that is commercially available for performing statistical evaluation consistent with procedures outlined in U.S. EPA's *Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities* (Unified Guidance; UG). Within the ChemStat™ statistical program (and the UG), tolerance limits were selected to perform the statistical calculation for background limits. Use of tolerance limits is a streamlined approach that offers adequate statistical power and is an acceptable approach under the CCR Rule. As such, upper tolerance limits (UTLs) were calculated for each of the CCR Appendix IV parameters, and, given that intra-well methods have been established for this site, a background UTL was calculated for each monitoring well and used to compare to the respective MCL or RSL. The following narrative describes the methods employed and the results obtained for the UTL calculations and the resulting GWPSs. The ChemStat™ output files are included as an attachment.

The set of background wells utilized for BRPP BABs includes MW-16-01, MW-16-02, MW-16-03, MW-16-04, and MW-16-09. The background data evaluation included the following steps:

- Review of data quality checklists for the baseline/background data sets for CCR Appendix IV constituents;
- Graphical representation of the baseline data as time versus concentration (T v. C) by well/constituent pair;
- Outlier testing of individual data points that appear from the graphical representations as potential outliers;
- Evaluation of percentage of nondetects for each baseline/background well-constituent (w/c) pair;
- Distribution of the data;
- Calculation of the UTLs for each cumulative baseline/background data set; and
- Establishment of GWPS as the higher of the MCL/RSL or the UTL for each Appendix IV constituent.

The results of these evaluations are presented and discussed below.

### Data Quality

Data from each sampling round were evaluated for completeness, overall quality and usability, method-specified sample holding times, precision and accuracy, and potential sample contamination. The review was completed using the following quality control (QC) information which at a minimum

## Technical Memorandum

included chain-of-custody forms, investigative sample results including blind field duplicates, and, as provided by the laboratory, method blanks, laboratory control spikes, laboratory duplicates. Data collected at MW-16-09 on 7/24/2017 were found to be anomalous due to high turbidity in the sample. Monitoring well MW-16-09 was resampled on 7/25/2017 with acceptable turbidity; therefore, the 7/24/2017 data was rejected and replaced with the 7/25/2017 data. The remaining data were found to be complete and usable for the purposes of the CCR monitoring program.

### Time versus Concentration Graphs

The time versus concentration (T v. C) graphs (Attachment A) do not show potential or suspect outliers for any of the Appendix IV parameters.

While variations in results are present, the graphs show consistent baseline data and do not suggest that data sets, as a whole, likely have overall trending or seasonality. However, due to limitations on CCR Rule implementation timelines, the data sets, with the exception of fluoride, are of relatively short duration for making such observations regarding overall trending or seasonality.

### Outlier Testing

No outliers were identified in the T v. C graphs. Therefore, outlier testing was not applicable.

As noted above, data collected at MW-16-09 on 7/24/2017 was found to be anomalous due to high turbidity in the sample. Therefore, these data were removed from the background data set and replaced with acceptable data from 7/25/2017. Outlier removal from the background data set is summarized in Table 1.

### Distribution of the Data Sets

ChemStat™ was utilized to evaluate each data set for normality. If the skewness coefficient was calculated to be between negative one and one, then the data were assumed to be approximately normally distributed. If the skewness coefficient was calculated as greater than one (or less than negative one) then the calculation was performed on the natural log (Ln) of the data. If the Ln of the data still determined that the data appeared to be skewed, then the Shapiro-Wilk test of normality (Shapiro-Wilk) was performed. The Shapiro-Wilk statistic was calculated on both non-transformed data and the Ln-transformed data. If the Shapiro-Wilk statistic indicated that normal distributional assumptions were not valid, then the parameter was considered a candidate for non-parametric statistical evaluation. The data distributions are summarized in Table 2.

### Tolerance Limits

Table 2 presents the calculated UTLs for the background/baseline data sets. As discussed above, the BRPP BABs CCR unit uses intra-well statistical methods; therefore, UTLs were calculated for each individual monitoring well. For normal and lognormal distributions, UTLs are calculated for 95 percent confidence using parametric methods. For non-normal background datasets, a nonparametric UTL is utilized, resulting in the highest value from the background dataset as the UTL. The achieved confidence levels for nonparametric tolerance limits depend entirely on the number of background data points, which are shown in the ChemStat™ outputs. The intra-well tolerance limits for each parameter were compared to the MCL/RSL and the higher value was established as the GWPS for that well.

## Technical Memorandum

### Groundwater Protection Standards

The resulting GWPSs were established as the higher of the MCL/RSL or the UTL for each Appendix IV constituent at each monitoring well. The GWPSs are summarized in Table 3.

**Notes:**

MCL - Maximum Contaminant Level, EPA Drinking Water Standards and Health Advisories, April 2012.

RSL - Regional Screening Level from 83 FR 36435.

UTL - Upper Tolerance Limit (95%) of the background data set.

GWPS - Groundwater Protection Standard. Appendix IV GWPS is the higher of the MCL/RSL and UTL.

ug/L = micrograms per liter

mg/L = milligrams per liter

pCi/L = picocuries per liter

## TABLE OF CONTENTS

1. PURPOSE.....	3
2. ASSUMPTIONS.....	3
3. SOLUTION .....	3
4. TRAVEL TIME SOLUTION.....	4

## 1. PURPOSE

The purpose of this calculation package is to calculate the vertical Darcy velocity of the model lithology for input in Fate and Transport numerical model at the Belle River Power Plant Bottom Ash Basins (BAB). Following Darcy velocity calculation, the solution is used to calculate the time of travel from the BABs to the Uppermost Aquifer.

## 2. ASSUMPTIONS

- Vertical flow is the dominant influence on contaminant transport; horizontal flow is not considered since a one-dimensional model was selected.
- Vertical hydraulic conductivity calculated in the laboratory using samples collected from borings is representative of subsurface conditions.

## 3. SOLUTION

The Darcy velocity ( $q$ ) through the model lithologies or layers is expressed in m/year =

$$= K(i) = K \left( \frac{H_1 - H_2}{l_1 - l_2} \right)$$

Where,

$K$  = vertical hydraulic conductivity (laboratory measured)

$i$  = vertical gradient

$H_1 - H_2$  = difference in hydraulic head between the BAB water level and the upper most aquifer potentiometric surface

$l_1 - l_2$  = distance in direction of flow

Thus:

$K$  = Geomean of Clay with Sand hydraulic conductivity value (data provided in Attachment 1) =  $2.15 \times 10^{-8}$  cm/s

$H_1$  = Total head at the bottom of BAB = 590 ft

$H_2$  = Average water level elevation from monitoring wells (data provided in Attachment 2) =  $574.28^1$  ft

$l_1$  = Bottom of ash pond = 580 ft

$l_2$  = Average elevation of well screen midpoints =  $470.98^1$  ft

$q$  = **Darcy velocity in m/year (= cm/s \* 315360) =  $1.02 \times 10^{-3}$  m/year**

<sup>1</sup> Value is an average taken from all monitoring wells

#### 4. TRAVEL TIME SOLUTION

Travel time ( $T$ ) through the model lithology is expressed in years =

$$T = t / \left( \frac{K * i}{n} \right)$$

Where:

$t$  = minimum model thickness

$K$  = vertical hydraulic conductivity (laboratory measured)

$i$  = vertical gradient

$n$  = effective porosity

Thus:

$t$  = Minimum model thickness per EVS model = 26.21 m

$K$  = Hydraulic conductivity =  $2.15 \times 10^{-8}$  cm/s

$i$  = Calculated using variables in Section 3 = 0.15

$n$  = Average of porosity data from Clay with Sand layer, converted to effective porosity using Sara (1994) = 0.34

$T$  = **Travel time in years (= s / 31536000) = 8,762 years**

**Note:** Time travel is not an input to Pollute model. It has been calculated to provide time estimate for the travel of water molecule from the bottom of BAB to top of uppermost aquifer.

## Notes:

1. Kv = vertical hydraulic conductivity as determined by the analysis of field and laboratory data summarized in Table M-1
2. Analysis of vertical hydraulic conductivity includes data from long term tests updated on 8/20/2021
3. Kv of Clay with Sand selected for the calculation of the Darcy velocity as the higher and thus more conservative value of the two layers; POLLUTE only allows one input for Darcy velocity
4. CoHD = Coefficient of Hydrodynamic Dispersion
5. Effective Porosity determined by multiplying estimated porosity from field and lab data by 0.81, based on data provided by Sara, 1994

Figure 8.10 Chloride and potassium concentration versus depth in sample for model D (modified from Rowe et al., 1988).

variation in concentration with depth in the soil at the end of each test. The consistency of results demonstrates the power of the analytical model (program POLLUTE) and provides some con-

Figure 8.11 Chloride and potassium concentration versus depth in sample for model E (modified from Rowe et al., 1988).

fidence in the parameters  $D$  and  $\rho K_d$  for the clay and source fluids examined.

To provide an indication of parameter variation that might be expected for a given soil, a number of tests were duplicated. The diffusion coefficient,  $D$ , for chloride was deduced for each model and ranged between 0.018 and 0.02 m<sup>2</sup>/a with an average value of 0.019 m<sup>2</sup>/a. This small variation in  $D$  does not appear to be related to small differences in Darcy velocity, nor does it appear to be particularly related to the nature of the associated cation (see Table 8.3). Rather, the variability from 0.018 to 0.02 m<sup>2</sup>/a is seen as an indication of the level of repeatability that may be achieved for this type of test.

The application of an effective stress to the soil sample adopted in these tests is not an essential part of the proposed technique for determining the parameters  $D$  and  $K_d$ . Tests performed for the particular combination of clay and permeants considered herein gave similar results both with and without the application of the effective stress. However, for some combinations of clay and permeant, shrinkage of the clay may occur in the absence of a confining stress and this can give quite misleading results (e.g., see Quigley and Fernandez, 1989). For these clays, and for GCLs (see Chapter 12), tests should be performed at an effective stress similar to that anticipated in the field.

### 8.3.2 Pure diffusion tests

In many cases, it is not necessary to perform an advection-diffusion test. Under these circumstances, a simple diffusion test can be performed for boundary conditions shown in Figure 8.2. In this test, the soil sample is placed in a Plexiglass cylinder by trimming the sample to a size marginally greater than the specimen and then pressing the specimen into the cylinder, using a cutting shoe attached to the cylinder, to perform the final trim. This procedure is found to work well for many clays. However, it does not work well for clays with a significant stone content because the

First line is the mean value

Second line is + one standard deviation about the mean

Adapted from: Rawls, W.J., D.C. Brakensiek, K.E. Saxton, 1982

The ratio of effective porosity to total porosity is 0.81 for Clay, and 0.88 for Silty Clay. Use 0.81 to be conservative.

## BAB\_ExtendedRun

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB Darcy

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00203$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB CoHD High

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.02375 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.02375 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB CoHD Low

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.01425 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.01425 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB ClayPoro High

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.45	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB ClayPoro Low

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.27	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB SandPoro High

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.019 m <sup>2</sup> /a	0.45	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB SandPoro Low

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.019 m <sup>2</sup> /a	0.20	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB ClayThick

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	13.99 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	35	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

## BAB ClayThin

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	11.03 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	19.29 m	40	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

## BAB SandThick

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	23.62 m	40	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

## BAB SandThin

THE DARCY VELOCITY (Flux) THROUGH THE LAYERS  $V_a = 0.00102$  m/year

### Layer Properties

Layer	Thickness	Number of Sublayers	Coefficient of Hydrodynamic Dispersion	Matrix Porosity	Distribution Coefficient	Dry Density
Clay	12 m	25	0.019 m <sup>2</sup> /a	0.37	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>
Clay with Sand	15.17 m	40	0.019 m <sup>2</sup> /a	0.34	0 m <sup>3</sup> /kg	1510 kg/m <sup>3</sup>

### Boundary Conditions

#### Constant Concentration

Source Concentration = 1 mg/L

#### Infinite Thickness Bottom Boundary

### Laplace Transform Parameters

TAU = 7   N = 20   SIG = 0   RNU = 2

### Calculated Concentrations at Selected Times and Depths

RE: Preliminary Alternate Liner Demonstration  
DTE Electric Company Belle River Power Plant  
Diversion Basin Coal Combustion Residuals Unit  
4505 King Road, China Township, Michigan

Dear Administrator Regan:

The DTE Electric Company (DTE Electric) is submitting the enclosed preliminary Alternate Liner Demonstration (ALD) to the U.S. Environmental Protection Agency (EPA) as a “place holder” and out of an abundance of caution to meet the November 30, 2021 date for submitting ALDs under the Part B rule.

As EPA has publicly acknowledged, the EPA has experienced unanticipated internal delays in reviewing and making decisions on the Part B applications that were submitted a year ago on November 30, 2020, and that this extended delay has practically eliminated the timeframe contemplated in the Part B rule for facilities to prepare their ALDs. Given this, EPA explains on their CCR Part B Implementation web page that they intend to “take actions to ensure that any facility approved to conduct a demonstration has the same amount of time anticipated by the current regulation to initiate and complete the demonstration after an approval.”

DTE Electric appreciates EPA’s commitment to take this corrective action and believes it is both necessary and appropriate. Regardless of the Agency’s internal delays DTE Electric proceeded expeditiously with the hydrogeological site characterization and laboratory study as detailed in the September 1, 2021 extension request due to analytical limitations. The extension request detailed the compatibility laboratory testing program results as of late August 2021, and projected termination criteria to be met by March 23, 2022. EPA has not yet responded to the extension request.

The enclosed preliminary ALD prepared by Geosyntec using preliminary data, concludes that the low permeability natural clay soils underlying the Belle River Power Plant Diversion Basin are consistently present across the basin and have sufficiently low hydraulic conductivity to prevent groundwater contamination at the solid waste boundary through the active life of the unit.

As allowed by the agency, electronic files were submitted to Richard Huggins, Mary Jackson, Michelle Long, and Jason Mills via email. If you have any questions regarding this submittal, please contact me at 313.235.0153 or [christopher.scieszka@dteenergy.com](mailto:christopher.scieszka@dteenergy.com)

Sincerely,

A handwritten signature in blue ink, appearing to read "Chris Scieszka", written in a cursive style.

## 1. INTRODUCTION

This report has been prepared to provide Preliminary Alternative Liner Demonstration (ALD) of Belle River Power Plant Diversion Basin (DB) Coal Combustion Residuals (CCR) Unit, one of two CCR units at the site, in accordance with 40 CFR Part 257 as amended on November 20, 2020 (CCR Rule). **Figure 1-1** provides the site location.

This report concludes that there is no reasonable probability that water from DB will cause releases to groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary over the projected active life of the CCR unit.

### 1.1 Background

DTE Electric Company (DTE) submitted the Alternate Liner Demonstration Application for the DB to the United States Environmental Protection Agency (USEPA) on November 30, 2020 [1] in accordance with the CCR Rule. Soon after, DTE started the field and laboratory investigation studies to meet the requirements of the CCR Rule.

One of the requirements of the CCR rule is to conduct hydraulic conductivity testing using site-specific permeant liquid. The CCR Rule acknowledges that these tests may last long such that the operator of the CCR unit may need to submit an extension request for the laboratory testing program, and submit a preliminary ALD.

DTE submitted an extension request due to “analytical limitation” under a separate cover, dated September 1, 2021 [2]. The extension request detailed the compatibility testing program results as of late August 2021, and projected termination criteria to be met by March 23, 2022. The EPA has not yet responded to the extension request.

### 1.2 Purpose

The purpose of this report is to provide ALD approach, analysis details, and present results based on available data in accordance with the CCR Rule. Although the Part B Rule does not require the submittal of a preliminary ALD by November 30, 2021 if an extension request is submitted in accordance with §257.71(d)(2)(ii)(A), DTE is providing this preliminary ALD as a “place holder” and out of an abundance of caution and with confidence in the performance of the liner system to comply with the requirement to submit an ALD by November 30, 2021. A final ALD will be submitted in accordance with the schedule expected to be included in the forthcoming EPA decisions.

### 1.3 Report Organization

The remainder of this report is organized as follows:

- Section 2 – provides the field and laboratory investigation details, information on site geology/hydrogeology, and conceptual site model details.
- Section 3 – provides results of hydraulic conductivity testing, termination criteria details, chemistry testing of site-specific water, and discussion of results.
- Section 4 – provides analysis approach, details, groundwater protection standards, and evaluation of results as to whether or not the DB meets the ALD requirement of the CCR Rule.
- Section 5 – provides a summary of the report.
- Section 6 – provides certification.
- Section 7 – provides references.

#### **1.4 Terms of Reference**

This report was prepared by Mike Coram C.P.G., Omer Bozok P.E., Jesse Varsho P.E., and reviewed by John Seymour, P.E. of Geosyntec.

## 2. CHARACTERIZATION OF SITE HYDROGEOLOGY

The CCR Rule requires the following:

*§257.71(d)(ii)(A) Characterization of site hydrogeology. A characterization of the variability of site-specific soil and hydrogeology surrounding the surface impoundment that will control the rate and direction of contaminant transport from the impoundment. The owner or operator must provide all of the following as part of this line of evidence:*

*(1) Measurements of the hydraulic conductivity in the uppermost aquifer from all monitoring wells associated with the impoundment(s) and discussion of the methods used to obtain these measurements;*

*(2) Measurements of the variability in subsurface soil characteristics collected from around the perimeter of the CCR surface impoundment to identify regions of substantially higher conductivity;*

*(3) Documentation that all sampling methods used are in line with recognized and generally accepted practices that can provide data at a spatial resolution necessary to adequately characterize the variability of subsurface conditions that will control contaminant transport;*

*(4) Explanation of how the specific number and location of samples collected are sufficient to capture subsurface variability if:*

*(i) Samples are advanced to a depth less than the top of the groundwater table or 20 ft beneath the bottom of the nearest water body, whichever is greater, and/or*

*(ii) Samples are spaced further apart than 200 ft around the impoundment perimeter;*

*(5) A narrative description of site geological history; and*

*(6) Conceptual site models with cross-sectional depictions of the site environmental sequence stratigraphy that include, at a minimum:*

*(i) The relative location of the impoundment with depth of ponded water noted;*

*(ii) Monitoring wells with screening depth noted;*

*(iii) Depiction of the location of other samples used in the development of the model;*

*(iv) The upper and lower limits of the uppermost aquifer across the site;*

*(v) The upper and lower limits of the depth to groundwater measured from monitoring wells if the uppermost aquifer is confined; and*

*(vi) Both the location and geometry of any nearby points of groundwater discharge or recharge (e.g., surface waterbodies) with potential to influence groundwater depth and flow measured around the unit.*

## **2.1 Introduction**

This section provides information on site geology and hydrogeology, data used in site characterization, a summary of ALD-specific field and laboratory study, and a conceptual site model built using the Environmental Visualization System (EVS).

## **2.2 Site Geology**

The surficial topography of St. Clair County is characterized by low-relief floodplain, stream terrace, and lakeshore deposits. The subsurface geology of the area is defined by glacial deposits, which range in thickness from 100 to 400 ft. These glacial sediments, including lacustrine, till, and sand and gravel outwash deposits, were deposited on the underlying bedrock. Throughout St. Clair County the underlying bedrock varies but is primarily fine-grained siliclastic rock, mostly shale with some sandstone [1].

The St. Clair River is the major surface water body in the county and runs along the eastern boundary of the county. Shallow regional groundwater flow would be expected to be towards east to the St. Clair River. The DB CCR Unit is located approximately one mile west of the St. Clair River.

### **2.2.1 Diversion Basin Site-Specific Geology**

The geology of St. Clair County consists of approximately 100 to 400 ft of glacial deposits, primarily lacustrine deposits, till, and, to a lesser extent, sand and gravel outwash, overlying a variety of bedrock surfaces. The glacial material underlying the DB appears to be glaciolacustrine clays with local sand lenses. The uppermost aquifer unit appears to be associated with ice contact directly above the bedrock surface (Bedford Shale).

The DB CCR Unit is underlain by 115 to 130 ft of unconsolidated sediments, with the upper aquifer unit directly above the Bedford Shale. The upper aquifer unit is laterally consistent throughout the DB CCR unit. During Geosyntec's ALD investigation in December 2020, cone penetration test (CPT) dissipation tests were completed. The CPT data confirm that the underlying deposits are

consistently low hydraulic conductivity units. Hydraulic conductivity of the underlying clay-rich deposits are summarized in Section 2.5.1.

The uppermost aquifer unit in the DB CCR unit is a confined, silty aquifer that directly overlies the Bedford Shale. It is approximately three to five ft in thickness and is encountered at approximately 115 to 130 ft bgs directly below the bottom of the DB. To the northwest, the silty aquifer transitions into a sandy aquifer and increases in thickness; specifically, in the vicinity of the Bottom Ash Basins (BABs) located to the northwest. For the purposes of this report, the silty aquifer unit within the DB CCR Unit is considered the “uppermost aquifer unit” and is further discussed in **Section 2.6**.

### **2.3 Uppermost Aquifer Field Testing and Hydrogeology**

TRC calculated the hydraulic conductivities within the CCR monitoring wells set within the upper portion of the uppermost aquifer using single well hydraulic conductivity tests (e.g., slug tests) performed in 2016 and 2021 by TRC. Test results are provided in **Appendix A** and are included in the EVS model. The monitoring well logs and construction details are presented in **Appendix B**. As calculated by TRC, the hydraulic conductivity of the uppermost aquifer using wells at the BABs CCR Unit area is approximately 0.13 ft/day (4.7E-5 cm/s).

### **2.4 Summary of Data Used for Site Characterization**

A host of data from three separate investigations was used to characterize the subsurface stratigraphy and soil characteristics for the site. Historical investigations included a 1973-1974 investigation performed by Bechtel and a 2016 investigation performed by TRC, all of which are included in the initial ALD Application [1]. Data from the 2020 ALD Investigation performed by Geosyntec was used to augment the data set. In total, these three investigations included 56 investigative locations that included 22 soil borings, 13 monitoring wells and 16 CPTs. **Figure 2-1** provides investigation locations.

Boring logs for the 1970s, 2016, and 2020 field investigations are provided in **Appendices C** through **E**, respectively. These investigations extend across the site and include DB and BABs, which is another CCR unit connected to DB (~ 400 ft northwest of DB). Considering the close proximity of both CCR units, field investigation data is used for both CCR units.

Field testing included pocket penetrometer tests on fine-grained soils, slug tests for the monitoring wells screened in the uppermost aquifer, and pore pressure dissipation tests (PPDs) at CPT locations. Lab testing included grain size distributions, Atterberg limits, water content, dry and/or total unit weight, specific gravity, and hydraulic conductivity testing. Type of tests, standards and number of tests are summarized in **Table 2-1**. Laboratory test results are provided in **Appendices F** through **H** for the 1970s, 2016, and 2020 laboratory studies, respectively.

Considering the extent of existing field investigation data, it is Geosyntec’s opinion that the data used in building this model is sufficient to capture the variability that may exist in soil conditions.

## **2.5 ALD-Specific Site Investigation Details**

The scope of work for the ALD-Specific Site Investigation (SI) was completed in December 2020 and included drilling and sampling, and advancing a CPT probe through the native soils. The purpose of the fieldwork was to obtain nominally undisturbed samples for hydraulic conductivity testing and to augment the existing data set to characterize the alternate liner materials in accordance with the CCR Rule. Investigations were conducted generally at 200-ft intervals but adjusted in the field as necessary to avoid underground utility lines, overhead power lines, and access issues, as needed. Investigations extended down to 100 ft bgs to an elevation approximately 490 ft, which is lower than groundwater level, and 20 ft below the nearest water body that is St. Clair River with a bottom elevation of approximately 525 ft.

The following sections provide a summary of the fieldwork completed during the SI.

### **2.5.1 Cone Penetrometer Tests**

Eight CPTs were completed around the DB in approximate 200 ft intervals along the east and south sides. Due to access issues to the area directly north and west of the DB, additional CPT locations were added to the south and southwest and CPT-08B/C was moved to the first accessible location west/northwest of the DB. The CPT locations are provided in **Figure 2-1**. CPTs were advanced from the ground surface to refusal or to approximately 100 ft bgs. Pore pressure dissipation tests were conducted to estimate in-situ hydraulic conductivity at select depths; at a minimum, these tests were conducted near the sonic borings and at the elevation near where undisturbed samples were collected for laboratory hydraulic conductivity testing.

In total, 12 dissipation tests were completed at CPTs advanced around DB, and 16 dissipation tests were completed at CPTs advanced around BABs. Hydraulic conductivity values were estimated to range between 7.97E-9 cm/s and 1.63E-6 cm/s around DB, and range between 9.76x10<sup>-9</sup> cm/s and 2.81E-6 cm/s around BABs. Hydraulic conductivity values are similar between soils underlying DB and BABs. Results are summarized in **Table 2-2**. These values are consistent with TRC’s 2018 Natural Clay Liner Equivalency Evaluation Report [1]. CPT logs are provided in **Appendix I1**, and PPD tests are provided in **Appendix I2**.

### **2.5.2 Sonic Drilling**

Six soil borings (three around the DB and three around the BABs) were advanced at the site to evaluate the subsurface geology, collect undisturbed samples for hydraulic conductivity testing, and collect additional soil samples for characterization of native soils. Soil samples were collected continuously in two to ten-foot sections from the ground surface to the termination of the soil

boring. Geosyntec staff were present to log each boring and describe the soil samples in accordance with the Unified Soil Classification System (USCS). Shelby tubes were collected from the DB embankment soils, and native soils at approximately 20 ft intervals from each of the sonic borings in accordance with ASTM D1587<sup>1</sup>. The soil borings were advanced to depths of approximately 100 ft-bgs. Sonic drilling locations are provided in **Figure 2-1**. Boring logs are provided in **Appendix E**. Soil stratigraphy is discussed in Section 2.6.

### 2.5.3 Laboratory Testing

A suite of index testing and hydraulic conductivity testing was conducted on select soil samples. Fourteen soil samples were collected from six borings for hydraulic conductivity testing from depths between five ft and 90 ft to capture soils conditions ranging from soft to very stiff soils. Details of hydraulic conductivity testing are provided in Section 3.

Index testing included:

- 24 Moisture Content tests (ASTM D2216)
- 4 Specific Gravity tests (ASTM D854)
- 22 Grain Size Mechanical Sieve tests (ASTM D6913)
- 21 Atterberg Limits tests (ASTM D4318)

Note that these tests quantities are included in **Table 2-1**. Test results are provided in **Appendix H**.

## 2.6 Conceptual Site Model

An EVS model was developed for the site based on data collected during the field investigations from the 1970s, 2016, and 2020. The EVS model centralized all the data to develop a comprehensive Conceptual Site Model (CMS). Based on the EVS model, the overall CMS of the Site lithology is relatively consistent with low hydraulic conductivity clay-rich deposits with non-interconnected sand seams at deeper depths. Within the DB CCR unit, the uppermost aquifer unit sits directly above the bedrock and is relatively consistent at approximately 10 ft thick across the DB CCR unit

Specific to the DB CCR unit, Cross-sections (**Figures 2-2** through **2-5**) were created from the EVS model and analyzed to determine the various changes in lithology within the clay confining unit

---

<sup>1</sup> ASTM D1587 – Standard Practice for Thin-walled Tube Sampling for Fine-grained Soils.

directly underlying the DB and the characteristics of the upper aquifer unit which sits directly on the bedrock. Upon review of the transects, the lithology beneath the BABs consists of (from the ground surface down) (1) clay, (2) clay with sand, (3) uppermost aquifer unit, and (4) shale bedrock. These units are consistent with historical reports and TRC's November 2020, Initial Application for Alternate Liner Demonstration [1]. There were some discrepancies, in that the second clay unit was described as silty instead of sandy. Based on CPT and geotechnical index testing during Geosyntec's 2020 ALD investigation, the lower clay was re-interpreted as "clay with sand" mainly due to sand seams that were encountered. It appears that the clay within the "clay with sand" unit is relatively consistent stiff gray clay. Therefore, the lithology directly underlying the DBs consist of the following:

- (1) Clay – 35 to 40 ft thick directly beneath the DB. This unit consists of mainly soft to medium stiff clay and minimal sand seams. None of the sand seams appear to be interconnected or considered aquifer unit.
- (2) Clay with sand – This unit was encountered at approximately 35 to 40 ft bgs with a thickness of approximately 80 to 90 ft. This unit consists of stiffer gray clay with increasing sand seams. Although there are more frequent sand seams, most are less than 2 ft in thickness and have hydraulic conductivity values greater than  $1 \times 10^{-7}$  cm/s except for one CPT dissipation test location which is discussed in more detail below. None of the sand seams appear to be interconnected or considered an aquifer unit. Consequently, because the sands are isolated, the unit behaves like a low hydraulic conductivity clay unit.
- (3) Uppermost Aquifer Unit – This unit was encountered at approximately 115 to 130 ft bgs. The thickness of the unit is relatively consistent at three to five ft thick and directly sits atop the bedrock. This silty unit is wet and considered the uppermost aquifer unit within the DB CCR unit. There is a transition from silty aquifer beneath the DB CCR unit to a thicker sandy aquifer beneath the BABs CCR located to the north/northwest. Both are considered the "uppermost aquifer unit" on the cross-sections and within the EVS model.
- (4) Shale bedrock – This unit was encountered at approximately 100-130 ft bgs.

During Geosyntec's 2020 investigation, CPT tests were conducted and dissipation tests were completed at CPT-08B, CPT-08C, CPT-11, CPT-12 and CPT-13B to estimate the hydraulic conductivity of the lithology. In addition, laboratory testing was conducted on individual samples from the three sonic borings around DB for long-term breakthrough potential and is further discussed in Section 3. Based on the review of the CPT dissipation data, values ranged from  $7.97\text{E-}9$  cm/s and  $1.63\text{E-}6$  cm/s around DB. The CPT-derived highest hydraulic conductivity value of  $1.63\text{E-}6$  cm/s was calculated at CPT-13B from a sand seam at 490 ft AMSL

(approximately 100 ft bgs) within the (2) clay with sand unit. Dissipation tests at CPT-13 and CPT-12 located next to CPT-13B indicated hydraulic conductivities less than  $1E-7$  cm/s. Therefore, the (1) clay and (2) clay with sand lithologies beneath the DB have adequate hydraulic conductivity values to be considered a low hydraulic conductivity unit and it is consistent with TRC's 2018 Natural Clay Liner Equivalency Evaluation Report [1].

Below the clay with sand is the uppermost aquifer unit that mainly consists of silt. The hydraulic head in the (3) uppermost aquifer unit associated with the DBs is approximately 575 ft AMSL [1] with a gradient to the west-northwest.

The bottom of the DB is at an elevation of approximately 576 ft and the bottom of the clay underlying the DBs is at an elevation of approximately 450 ft AMSL, thus more than 120 ft of low hydraulic conductivity clay-rich deposits ((1) clay and (2) clay with sand) separate the bottom of the DB CCR unit from the underlying (3) uppermost aquifer unit.

### 3. POTENTIAL FOR INFILTRATION

The CCR Rule requires:

*§257.71(d)(ii)(B) Potential for infiltration. A characterization of the potential for infiltration through any soil-based liner components and/or naturally occurring soil that control release and transport of leachate. All samples collected in the field for measurement of saturated hydraulic conductivity must be sent to a certified laboratory for analysis under controlled conditions and analyzed using recognized and generally accepted methodology. Facilities must document how the selected method is designed to simulate on-site conditions. The owner or operator must also provide documentation of the following as part of this line of evidence:*

- (1) The location, number, depth, and spacing of samples relied upon is supported by the data collected in paragraph (d)(1)(ii)(A) of this section and is sufficient to capture the variability of saturated hydraulic conductivity for the soil-based liner components and/or naturally occurring soil;*
- (2) The liquid used to pre-hydrate the samples and measure long-term hydraulic conductivity reflects the pH and major ion composition of the CCR surface impoundment porewater;*
- (3) That samples intended to represent the hydraulic conductivity of naturally occurring soils (i.e., not mechanically compacted) are handled in a manner that will ensure the macrostructure of the soil is not disturbed during collection, transport, or analysis; and*
- (4) Any test for hydraulic conductivity relied upon includes, in addition to other relevant termination criteria specified by the method, criteria that equilibrium has been achieved between the inflow and outflow, within acceptable tolerance limits, for both electrical conductivity and pH.*

#### 3.1 Soil Sample and Site-Specific Water Details

##### 3.1.1 Soil Samples for Hydraulic Conductivity Testing

Fourteen soil samples were collected for hydraulic conductivity testing. Considering the extent of existing field investigation data, including CPTs, earlier borings, Geosyntec believes that the collected samples are sufficient to capture the variability of hydraulic conductivity in natural soils.

##### 3.1.2 Site-Specific Water Testing and Results

Site-specific CCR porewater samples were collected from both DB and the BABs for geochemical analyses to determine the representative composition of an “aggressive” solution for use in the

compatibility portion of the hydraulic conductivity testing. Due to the high turbidity of basin waters, samples were filtered through a 0.45-micron filter to evaluate dissolved concentrations. Site-specific water samples were tested for CCR Rule Appendix III and Appendix IV parameters as well as additional major cations (sodium, magnesium, potassium), anions (total alkalinity), iron, and manganese.

All water samples were found to be slightly basic, with pH concentrations ranging from 7.87 to 9.01 SU. TDS concentrations of all three samples are similar, ranging from 200 to 300 mg/L. All three samples have TDS concentrations < 1000 mg/L, which is defined by the United States Geological Survey (USGS) as “freshwater”. DB and the BABs samples have similar major ion compositions, as illustrated on the Piper diagram in **Figure 3-1**. The anion composition is very similar for all three samples and consists of predominantly sulfate with some alkalinity and very little chloride. The cation composition is predominantly calcium and monovalent cations (potassium/sodium), with a smaller proportion of magnesium. The DB sample has a slightly higher relative percentage of calcium and lower monovalent cations compared to the BABs samples.

The analytical results are provided in **Appendix J** and tabulated in **Table 3-1**. Results were used to calculate total ionic strength for each sample. Total ionic strength is a measure of the combined ion concentrations in a solution and can represent the salinity of a sample. Total ionic strength was calculated for each sample using geochemical modeling software Geochemist’s Workbench (GWB) v12.0.4. The GWB thermodynamic dataset ‘thermo.com.V8.R6\_.tdat’ was used for the calculations in order to incorporate all tested parameters. Analytical results for each parameter were input into GWB in units of milligrams per liter (mg/L) and the ionic strength of each sample was calculated in units of molality (m).

Both BAB samples contained similar ionic strength values (0.0088 and 0.0080 m) compared to the slightly higher ionic strength of the DB sample (0.0106 m). Thus, the DB sample is considered to be the more aggressive solution and was used for compatibility testing as described in Section 3.2.

### **3.2 Hydraulic Conductivity Testing Procedure and Termination Criteria**

All 14 soil samples were tested for hydraulic conductivity,  $k$  using deionized water in accordance with ASTM D5084 [3] to establish a baseline  $k$  reading. Then, six of the samples those exhibiting high and low  $k$  values were selected for compatibility testing in accordance with ASTM D7100 [4] using site-specific water. The use of ASTM D7100 is discussed in the preamble of the CCR Rule and deemed appropriate by USEPA.

ASTM D7100 termination criteria require the following conditions:

- The ratio of outflow to inflow is between 0.75 and 1.25. The hydraulic conductivity is considered steady if four or more consecutive hydraulic conductivity determinations fall

within  $\pm 25$  % or better of the mean value for hydraulic conductivity,  $k \geq 3E-8$  cm/s or within  $\pm 50$  % or better for  $k < 1E-8$  cm/s, and a plot or tabulation of the hydraulic conductivity versus time shows no significant upward or downward trend;

- At least 2 pore volumes (PV) of flow have passed through the sample; and
- pH and electrical conductivity of effluent, is within 10% of that for the influent with no significant increasing or decreasing trends

### 3.3 Hydraulic Conductivity Test Results and Assessment

Preliminary results are provided in **Appendix K** as of August 20, 2021 and summarized in **Table 3-2**. The table provides sample ID, the start date for testing, amount of flow passed through a sample for a given duration of time, hydraulic conductivity values, and projected date for completing 2 PV of flow.

In addition, a set of figures created for each sample providing insight into the progression of:

- PV of flow with time.
- hydraulic conductivity with time.
- hydraulic conductivity with PV;
- pH of inflow and outflow with time; and
- Electrical conductivity (EC) with time.

Progression of different parameters is provided from **Figure 3-2** through **3-31**.

Overall, the hydraulic conductivity,  $k$  value of samples range between  $8.2E-09$  and  $2.8E-08$  (cm/s). The amount of PV of flow that has passed through the samples ranges from 0.8 to 2.3. As of August 20, 2021, two of the samples have reached the 2 PV criteria. The remaining samples are projected to reach 2 PV March 2022; this is based on linear extrapolation between PV at known dates and assumes  $k$  stays relatively constant. Overall, the PV of flow is progressing linearly towards the 2 PV criteria. Hydraulic conductivity values are generally flat and can be considered steady.

pH values are provided in **Table 3-3**. In general, the average pH of inflow ranges from 8.2 to 8.4, and the average pH of outflow ranges from 8.1 to 8.4. The pH of outflow is within 10 percent of inflow.

EC values are provided in **Table 3-4**. In general, the average EC of inflow ranges from 609 to 680, and the average EC of outflow ranges from 778 to 2146. The EC of outflow are not within the 10 percent of inflow; they are projected to meet the termination criterion by the end of December 2021. This date is based on the convergence of linear extrapolations of the data.

**Table 3-5** summarizes if the sample has reached the termination criterion for PV, pH, EC, and the approximate projected date for reaching the termination criteria. As summarized in the table, samples have not reached all the termination criteria; pH has received termination criterion, and two of the samples have reached the PV criterion; none of the samples have reached the EC criterion. Based on available data, Geosyntec expects the last sample to reach termination criteria by the end of March 23, 2022.

The results do not include inflow vs outflow data. The main reason is that the project team had decided to keep the inflow constant, which provides more stable gradient across the sample, more accurate estimation of  $k$ , faster testing, and more control in the testing procedure. It is Geosyntec's opinion that the inflow/outflow criterion would be reached by the time other criteria is reached.

#### 4. FATE AND TRANSPORT MODEL ANALYSES

The CCR Rule requires:

*§257.71(d)(ii) (C) Mathematical model to estimate the potential for releases. Owners or operators must incorporate the data collected for paragraphs (d)(1)(ii)(A) and (d)(1)(ii)(B) of this section into a mathematical model to calculate the potential groundwater concentrations that may result in downgradient wells as a result of the impoundment. Facilities must also, where available, incorporate the national-scale data on constituent concentrations and behavior provided by the existing risk record. Application of the model must account for the full range of site current and potential future conditions at and around the site to ensure that high-end groundwater concentrations have been effectively characterized. All the data and assumptions incorporated into the model must be documented and justified.*

*(1) The models relied upon in this paragraph (d)(1)(ii)(C) must be well- established and validated, with documentation that can be made available for public review.*

*(2) The owner or operator must use the models to demonstrate that, for each constituent in appendix IV of this part, there is no reasonable probability that the peak groundwater concentration that may result from releases to groundwater from the CCR surface impoundment throughout its active life will exceed the groundwater protection standard at the waste boundary.*

*(3) The demonstration must include the peak groundwater concentrations modeled for all constituents in appendix IV of this part attributed both to the impoundment in isolation and in addition to background.*

##### 4.1 Introduction

A fate and transport model analysis have been performed to evaluate whether the peak groundwater concentrations that may result from releases to the groundwater from the DB exceeds the groundwater protection standards (GWPS) at the waste boundary throughout its active life.

The model considers flow of CCR pore water Constituents of Concern (COC) migrating through the bottom of CCR unit down to the uppermost aquifer. The model does not consider additional migration of COC horizontally to the waste management boundary. If considered, the horizontal groundwater flux would reduce the concentrations of the COC; consequently, the model presents a conservative assessment. As discussed later in Section 4.6.1 the results of the model predicts COCs concentrations that are very low such that there is no reasonable probability that water from DB will cause releases to groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary over the projected active life of the CCR unit.

## 4.2 Groundwater Protection Standards

Groundwater samples from TRC's 2016 and 2017 sampling events were tested for Appendix IV COCs and represent eight rounds of background groundwater data. The data were used to calculate site-specific background levels (Background) for Appendix IV COCs. **Appendix L** provides the memorandum describing the statistical calculations.

To develop GWPS for the ALD assessment, the federal Maximum Contaminant Level (MCL), Regional Screening Levels, and Background (whichever is higher) were evaluated and the highest value was selected as the GWPS in accordance with the CCR Rule. Where MCL are not available Regional Screening Levels were used. GWPS are provided in **Table 4-1**.

## 4.3 Consideration of Background Groundwater Concentrations

The background has been considered and is a factor when determining if GWPS has been exceeded. At the DB, naturally occurring background concentrations are generally much lower than the GWPS. The predicted groundwater concentrations and peak groundwater background concentrations are further discussed in Section 4.6.1.

## 4.4 Leachate Quality Results

Porewater (i.e. leachate) quality samples from both DB and the BABs were collected in December of 2020 and January of 2021; samples were analyzed for Appendix III and IV parameters by ALS Environmental in Holland, MI. Analytical results were compared for each parameter and the highest leachate concentration was used as the established concentration of the constituent ( $C_o$ ) when calculating the predicted groundwater concentrations ( $PGC_i$ ), as discussed further in this Section. The leachate quality data is summarized in **Table 4-2**.

In addition to the site-specific leachate concentrations, 90<sup>th</sup> percentile concentrations from the 2014 EPA study [5] were considered in the analysis. This data is summarized in **Table 4-2**.

## 4.5 Fate and Transport Model

### 4.5.1 Analysis Model

A one-dimensional fate and transport model was designed to further understand the potential for contaminant transport from the CCR units to the uppermost aquifer. The model was developed with a contaminant transport process through the clay and clay with sand layers under the DB. Contaminant transport processes are discussed in Section 4.5.2.1 below.

The modeling program POLLUTE [6] was selected for the one-dimensional fate and transport evaluation. The data input for POLLUTE acquires all the input parameters, performs calculations

for individual transport processes, and then uses the semi-analytical solution for the various transportation process (see Section 4.5.2) to yield predicted concentrations at the various specified times and distances.

Model setup and inputs are discussed in detail in the following sections and are summarized via layers in **Figure 4-1**.

## 4.5.2 Proposed Mathematical and Associated Computer Model

### 4.5.2.1 *Mathematical Model*

The potential transport mechanisms that may occur at the DB for the various modeled layers include advection, mechanical dispersion and diffusion. For porous media, these transport mechanisms can be represented by the following one-dimensional flow equation [7]:

$$\text{Equation No. 1: } n \frac{\delta c}{\delta t} = nD \frac{\delta^2 c}{\delta z^2} - V_{\alpha} \frac{\delta c}{\delta z} - \rho K_d \frac{\delta c}{\delta t} - n\lambda c$$

Where:

c = concentration at any point

D = Coefficient of hydrodynamic dispersion in the vertical direction

n = porosity of the geologic layer

K<sub>d</sub> = distribution coefficient

V<sub>α</sub> = Darcy Velocity in the vertical direction

ρ = dry density of soil

λ = decay constant of the contaminant species

t = time

POLLUTE utilizes the transport phenomena as governed by Equation No. 1

### 4.5.2.2 *Predicted Groundwater Concentrations*

This model uses an initial concentration value of one (1), which represents a unit concentration of any constituent in the leachate. The results from the model can thus be used as a prediction factor for estimating the future concentration of any constituent of concern in groundwater. Multiplying the output prediction factor by the initial leachate concentration provides the predicted

groundwater concentration at the end of the model run. The following equation (Equation No. 2) illustrates this concept:

$$\textit{Equation No. 2:} \quad \text{PGC}_t = \text{PF}_t * \text{C}_o$$

Where:

$\text{PGC}_t$  = predicted groundwater concentration after t years.

$\text{PF}_t$  = prediction factored after t years, which is the output of the model.

$\text{C}_o$  = established leachate concentration of the constituent of concern.

### 4.5.3 Fate and Transport Model Inputs

#### 4.5.3.1 *Initial Leachate or Source Concentration*

The initial leachate concentration input value used was one (1). This value is unitless because it represents unit leachate concentration of any given constituent. Therefore, the model results represent a fraction of the initial leachate concentration for any constituent.

#### 4.5.3.2 *Number of Layers and Layer Thickness*

Two layers were modeled at the site: the clay layer and the clay with sand layer. At the DB, the clay layer has an average thickness of 36 ft; the clay with sand layer has an average thickness of 84 ft. The average thickness of each layer was derived from an isopach map generated by subtracting the surface representing the bottom of the layer from the surface representing the top of the layer, and averaging the difference over the extent of DB footprint; model documentation for the average thickness of each layer can be found in **Appendix L**.

POLLUTE also allows layers to be subdivided into sublayers, which allows the predicted concentration distribution within a layer to be calculated. The clay layer was divided into 20 sublayers at the DB. The clay with sand layer was divided into 50 sublayers at the DB.

#### 4.5.3.3 *Modeling Period*

The model was run for the operating period of 55 years. This modeling period captures the amount of time elapsed from the 1980s, when CCR unit(s) operations started, to 2034, which is the end of the projected active life of DB.

#### 4.5.3.4 *Talbot Parameters*

POLLUTE uses a Laplace transform to find the solution to the advection-dispersion equation. The numerical inversion of the Laplace transform depends on the Talbot parameters. The model provides default values for the parameters or they can be selected by the user. The default Talbot parameter were used in this demonstration [8].

#### 4.5.3.5 *Boundary Conditions*

POLLUTE allows the user to select between multiple upper and lower boundary conditions. The top boundary condition typically represents the CCR unit invert, as a potential source. The top boundary can be specified as either zero flux, constant concentration, or finite mass. A constant concentration was assumed as it results in conservative model results since it assumes that the leachate quality will remain constant at the maximum measured values over time.

The lower boundary can be specified as either zero flux, constant concentration, fixed outflow, or infinite thickness. For this model, an infinite thickness lower boundary was used; thus, the model output is a prediction factor of contaminant concentration in groundwater at the interface between the clay with sand layer and the underlying uppermost aquifer.

#### 4.5.3.6 *Darcy Vertical Velocity*

POLLUTE requires a Darcy velocity to be input for the model as a whole. The Darcy velocity was calculated for each basin using a vertical gradient and the vertical hydraulic conductivity of the clay layer. For the DB, the vertical gradient was calculated using hydrogeologic data from the uppermost aquifer and the elevation of the maintained water level within the CCR surface impoundment. These parameters were chosen to produce a conservative value for the Darcy velocity. Darcy velocity value of 2.03E-4 m/year was calculated for the DB as provided in **Appendix L**. The hydraulic conductivity value used for the calculation of Darcy velocity is the average (geometric mean) of historical and current lab testing program vertical hydraulic conductivity data.

#### 4.5.3.7 *Hydrodynamic Dispersion Coefficient*

The vertical coefficient of hydrodynamic dispersion is a required input for each layer within the POLLUTE model. The hydrodynamic dispersion coefficient is calculated using Equation No. 3:

$$\text{Equation No. 3: } D = D^* + av$$

Where:

D = the hydrodynamic dispersion coefficient (m<sup>2</sup>/year);

- D\* = the effective diffusion coefficient (m<sup>2</sup>/year).
- a = the dispersivity (m);
- v = the groundwater seepage velocity (m/year).

For this demonstration, the coefficient of hydrodynamic dispersion for chloride was used, as calculated by Rowe et al. [9] a value of 0.019 m<sup>2</sup>/year was input into the model. The coefficient for chloride was chosen as it is considered to have a high capacity for diffusion compared to other constituents of interest, thus it is a conservative constituent to model among the constituents of concern.

Due to the low Darcy velocity in the clay and clay with sand units (2.03E-4 m/year), sum of (av) is essentially zero; and therefore, the dominant mechanism for containment transport is diffusion.

#### 4.5.3.8 *Effective Porosity and Density Input*

The average porosity of each model layer was estimated using laboratory data as discussed in Section 2. The model shows good agreement between porosity values and geologic layers, with the overlying clay unit displaying visibly lower porosities than the underlying clay with sand unit. An average of 46 percent porosity was used for the clay layer, while an average of 42 percent porosity was used for the clay with sand layer.

Based on empirical data provided by Sara (1994) [10], the laboratory porosity data was converted to effective porosities. An effective porosities values of 0.37 and 0.34 for the clay and clay with sand layers were utilized, respectively.

Density values from laboratory testing were also used to determine a suitable model input. The average density of 1,500 kg/m<sup>3</sup> (94.2 pcf) was assessed from the available data; this value was used in the POLLUTE model.

#### 4.5.3.9 *Adsorption Coefficient and Degradation*

Adsorption and degradation of constituents can play a significant role in the impedance of contaminant migration in the subsurface. Within POLLUTE, the adsorption coefficient simulates the impedance of constituents or sorption of containments in the modeled layers, while degradation simulates the breakdown of contaminants over time. In this model, adsorption and degradation are assumed to be zero, which provides a more conservative model result.

## 4.6 Fate and Transport Analysis Results and Evaluation

### 4.6.1 Fate and Transport Baseline Model Results

The modeling was performed to evaluate predicted groundwater quality based on the hydrogeology of the site. At the DB, the baseline model calculated a  $PF_t$  of  $8.63E-40$ . With both the  $C_o$  and  $PF_t$  established, the  $PGC_t$  (i.e. predicted concentration) was calculated and compared to the established GWPS for the DB. As provided in **Table 4-2**, the predicted groundwater quality results, and the 90<sup>th</sup> percentile concentrations from the 2014 EPA study [5] are below the GWPS levels. In addition, the predicted concentrations were added to the highest concentrations that were measured in 2016-2017 groundwater sampling events, and compared to the GWPS. The combined results from predicted concentrations and the highest measured concentrations are below the GWPS (see **Tables 4-3**). Therefore, no impacts to groundwater above GWPS are predicted over the duration of DB's active life

The driving mechanism for the transport is chemical diffusion because the advective flow would take more than a thousand years for a water molecule to travel from the bottom of DB to the uppermost aquifer. **Appendix L** provides calculations for the time of travel.

The baseline model outputs for the DB are included in **Appendix M**.

### 4.6.2 Sensitivity Analysis

Many of the model inputs are specific to the site. Given the potential for sampling bias, uncertainty, and natural variation, a sensitivity analysis was conducted to evaluate the impact on the variation of the model inputs. The analysis focused on changes to the model output, or  $PF_t$ , given a variation to a single model input as discussed in the following sections. A summary of the sensitivity analyses model input values is provided in **Table 4-4**. The resulting  $PF_t$  from each sensitivity analysis was compared to a threshold prediction value,  $PF_{\text{threshold}}$ . The  $PF_{\text{threshold}}$  value represents the  $PF_t$  at which impacts to groundwater are predicted for Appendix IV COCs at the top of the uppermost aquifer under the CCR unit; the threshold value is 0.24 for the DB.  $PF_{\text{threshold}}$  is calculated using the Equation No. 4:

$$\text{Equation No. 4: } PF_{\text{threshold}} = \min \left\{ \frac{GWPS_1}{C_1}, \frac{GWPS_2}{C_2}, \dots, \frac{GWPS_i}{C_i}, \dots, \frac{GWPS_n}{C_n} \right\}$$

Where:

$PF_{\text{threshold}}$  = Threshold Prediction Factor

$GWPS_i$  = Groundwater Protection Standard for Constituent 'i'

$C_i$  = Maximum porewater concentration of the COC 'i'

#### 4.6.2.1 *Darcy Velocity*

A sensitivity analysis was completed to evaluate the impact of Darcy velocity changes. A Darcy velocity of 4.07E-4 m/year was selected as the value to use for this analysis. This value is double the baseline value calculated during this demonstration and thus serves as a suitable value for input to the sensitivity analysis.

#### 4.6.2.2 *Coefficient of Hydrodynamic Dispersion*

Model sensitivity to the coefficient of hydrodynamic dispersion was evaluated by increasing and decreasing the input value by 25%. The initial input value was derived from laboratory testing (Rowe et al., 2004) [9], and thus a 25% increase and decrease is considered a satisfactory variation for sensitivity analysis.

#### 4.6.2.3 *Porosity and Effective Porosity*

Model sensitivity to the porosity and effective porosity was evaluated by increasing and decreasing the input value by the minimum and maximum range of values calculated from the laboratory results.

#### 4.6.2.4 *Layer Thickness*

The isopach maps (**Appendix L**) were used to calculate the maximum and minimum thickness for the clay and clay with sand layers. Using those values as inputs, four additional models were run for each CCR unit to evaluate model sensitivities to layer thickness; in each model only one variable was changed.

#### 4.6.2.5 *Modeling Period*

The modeling period used was 55 years (the “baseline”). To further evaluate the impact of modeling runtime on the resultant PF<sub>t</sub>, one model was run with a modeling period of 85 years, to capture the post-closure care time period, though DTE intends to close the DB by removal.

#### 4.6.2.6 *Sensitivity Results*

Additional fate and transport model runs were completed to evaluate model sensitivities to changing model inputs. As shown in **Table 4-5** using more conservative model input parameters resulted in a PF<sub>t</sub> values ranging from 7.41E-47 to 1.54E-32. This demonstrates that the DB will not impact groundwater quality assuming conditions more conservative than the baseline scenario. The sensitivity modeling results are presented in **Table 4-5** whereas the model outputs are included in **Appendix M**.

### 4.6.3 Reliability of Computer Model

The computer-based transport model used for this analysis is based on rigorous and proven analytical solutions to the advection-dispersion equation for layered deposits. These equations were derived with the intent of modeling the physical and chemical transport of contaminants from waste impoundments. Widespread use, comprehensive documentation, and abundant publications (Talbot, 1979 [8]; Rowe, 1987 [11]; Rowe and Booker, 1987 [12]; Rowe, 1988 [7]; and Rowe and Booker, 1989 [13]) lend to the versatility of this modeling approach for assessing groundwater impacts. The outputs obtained from models conducted in POLLUTE can be compared to those obtained using other approaches to solving the advection-dispersion equation.

### 4.6.4 Degree of Conservativeness in Model Results

Input parameters for the baseline models were based on site-specific data whenever possible. When not possible, input values were derived from an understanding of the site and relevant peer-reviewed literature. If a high degree of uncertainty was present, conservative input values were selected. A summary of the various conservative assumptions is listed below:

- The maximum measured leachate (i.e., porewater) concentration for each constituent was used for the fate and transport model prediction table;
- Constant leachate concentration or a constant mass was used for the entire modeling period. A specific mass could have been assumed for modeling purposes which would have resulted in decreased leachate concentrations over time but to be conservative the model considered constant leachate concentration over time;
- Adsorption can significantly reduce the concentrations of metal constituents as they move through soils, especially clays which would retard or slow down the migration. To be conservative, the model assumed no adsorption would occur over time;
- Degradation of leachate (input values) through either biologic or chemical process was assumed not occur during the modeling period. By assuming no degradation, the model overestimates the predicted groundwater quality over time; and
- The CCR Rule requires compliance at the waste boundary. The analysis only considers vertical flow from the bottom of FAB to the top of the uppermost aquifer; the analysis does not consider a 2-D flow towards the waste boundary, which would further lower the predicted concentration levels for COCs.

## 5. SUMMARY

This Preliminary ALD has been prepared to assess if the DB CCR unit meets the ALD requirements per the CCR Rule. The data included comprehensive field and laboratory investigation data collected from the 1970s to 2020. The 2020 field and laboratory investigation studies were conducted specifically to augment the data set and to address the CCR Rule requirements. The data were integrated into an EVS model to create a comprehensive CSM to understand the DB lithology beneath the CCR unit and as a basis for the Fate and Transport analysis.

Site-specific water was collected from DB and BABs and tested to assess which one of the CCR units had the more aggressive water. Water from DB was deemed to be more aggressive and used for compatibility testing to estimate the impacts on hydraulic conductivity of soil samples. The testing program is still underway. The most current results from the testing have been used in this ALD.

A comprehensive subsurface stratigraphy model was created using the augmented data set and processing it through the EVS. Following, Fate and Transport analysis was conducted to assess whether there is a reasonable probability that water from DB may result from releases to groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary.

The Fate and Transport analysis was conducted for the operating time period of 55 years (“baseline”), which captures the amount of time elapsed from the 1980s, when CCR unit operations started, to 2034, which is the end of the projected active life of DB.

The analysis considered different contaminant transport mechanisms including, advection, dispersion, and diffusion. The analysis indicates that advective flow would take more than a thousand years for a water molecule to travel from the bottom of DB to uppermost aquifer. Therefore, the analysis results indicate that, due to the low permeability nature of the in-situ unconsolidated materials, chemical diffusion is the dominant transport mechanism as opposed to advection or seepage flow. Hence, the current hydraulic conductivity testing described in Section 3 is sufficient to characterize hydraulic conductivity and demonstrate the performance of the alternate liner system as it relates to advection or seepage flow. It is highly unlikely that running the samples until they achieve termination criteria would change the outcome of this study, and therefore, the tests do not need to extend until March 2022.

The Fate and Transport analysis was augmented with a sensitivity analysis to account for sampling bias, uncertainty, and natural variation in site-specific inputs. Predicted groundwater concentrations for both the baseline and sensitivity analyses are below GWPS. The analysis results show that there is no reasonable probability that water from DB will result in releases to

groundwater throughout its active life that will exceed the groundwater protection standard at the waste boundary over the projected active life of the CCR unit.

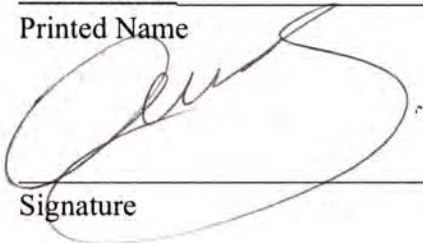

**6. CERTIFICATION**

**CCR Unit:** DTE Electric Company; Belle River Power Plant, Diversion Basin (DB)

I, Omer Bozok, being a Registered Professional Engineer in good standing in the State of Michigan, do hereby certify in accordance with the CCR Rule, to the best of my knowledge, information, and belief, that the information contained in this plan has been prepared in accordance with the accepted practice of engineering and that the DB meets the requirements of the Alternative Liner Demonstration per the CCR Rule.

Thallium	mg/L	MCL	1.0E-03	3.5E-42	1.0E-03	2.0E-03	Pass

**Notes:**

MCL - Maximum Contaminant Level, EPA Drinking Water Standards and Health Advisories, April 2012.

RSL - Regional Screening Level from 83 FR 36435.

UTL - Upper Tolerance Limit (95%) of the background data set.

GWPS - Groundwater Protection Standard. Appendix IV GWPS is the higher of the MCL/RSL and UTL.

mg/L = milligrams per liter

pCi/L = picocuries per liter

\* - Anomalously high value removed, failed Dixon's Test for outliers at 1% significance

**Table 4-4 – Sensitivity Analysis Model Inputs**

	Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis	Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis		Baseline	Sensitivity Analysis
<i>Layer Properties</i>	Thickness (m)	Max Thickness (m)	Min Thickness (m)	Dv (m/yr)	Dv (m/yr)	CoHD	CoHD +25%	CoHD -25%	Total Porosity	Max Porosity	Min Porosity	Effective Porosity	Eff. Porosity Max	Eff. Porosity Min	Modeling Period (years)	Modeling Period (years)
Clay	11.12	12.13	10.70	2.03E-04	4.07E-04	0.019	0.024	0.014	0.46	0.56	0.34	0.37	0.45	0.28	55	110
Clay with Sand	25.66	26.82	24.66	2.03E-04	4.07E-04	0.019	0.024	0.014	0.42	0.55	0.24	0.34	0.45	0.20	55	110

Dv = Vertical Darcy Velocity

CoHD = Coefficient of Hydrodynamic Dispersion

**Table 4-5 – Sensitivity Analysis Results Prediction Factors**

<b>Diversion Basin Sensitivity Analysis</b>			
<b>Model Name</b>	<b>Description</b>	<b>Prediction Factor</b>	<b>Pass?*</b>
DB_Baseline	Baseline model for the Bottom Ash Basins.	8.63E-40	YES
DB_ExtendedRun	Model runtime was extended from 55 years to 85 years.	1.54E-32	YES
DB_Darcy	Darcy velocity was doubled.	1.51E-39	YES
DB_CoHD_High	Coefficient of Hydrodynamic Dispersion was increased by 25%.	1.12E-35	YES
DB_CoHD_Low	Coefficient of Hydrodynamic Dispersion was decreased by 25%.	7.41E-47	YES
DB_ClayPoro_High	Used the highest effective porosity in clay interval; derived from laboratory data in project database.	9.16E-40	YES
DB_ClayPoro_Low	Used the lowest effective porosity in clay interval; derived from laboratory data in project database.	7.87E-40	YES
DB_SandPoro_High	Used the highest effective porosity in clay with sand interval; derived from laboratory data in project database.	6.77E-40	YES
DB_SandPoro_Low	Used the lowest effective porosity in clay with sand interval; derived from laboratory data in project database.	1.42E-39	YES
DB_ClayThick	Used thickest clay interval seen in boring/well; derived from project database.	5.69E-41	YES
DB_ClayThin	Used thinnest clay interval seen in boring/well; derived from project database.	2.66E-39	YES
DB_SandThick	Used thickest clay with sand interval seen in boring/well; derived from project database.	3.77E-41	YES
DB_SandThin	Used thinnest clay sand interval seen in boring/well; derived from project database.	1.18E-38	YES
* Indicates value less than $PF_{\text{threshold}}$ , as discussed in Section 4.6.2.

MW-16-07 RISING HEAD SLUG TEST

Data Set: P:\...\MW-16-07\_OUT.aqt  
 Date: 05/22/17

Time: 13:44:45

PROJECT INFORMATION

Company: TRC Environmental Corporation  
 Client: DTE EC BRPP CCR  
 Project: 231828.0003.0000  
 Location: China Township, MI  
 Test Well: MW-16-07  
 Test Date: 4/13/16

AQUIFER DATA

Saturated Thickness: 2. ft

Anisotropy Ratio (Kz/Kr): 1.

WELL DATA (MW-16-07)

Initial Displacement: 0.88 ft  
 Total Well Penetration Depth: 124.4 ft  
 Casing Radius: 0.08333 ft

Static Water Column Height: 124.4 ft  
 Screen Length: 5. ft  
 Well Radius: 0.08333 ft

SOLUTION

Aquifer Model: Confined  
 K = 7.212E-5 cm/sec

Solution Method: Bouwer-Rice  
 y0 = 0.7909 ft

## **2021 Slug Test Results**

**2021 Hydraulic Conductivity Results Summary**  
**DTE Electric Company Belle River Power Plant Bottom Ash Basins and Diversion Basin**  
**4505 King Road, China Township, Michigan**

Test	WC (ft)	K (cm/s)	K (ft/day)	Comment/K Geometric mean (cm/s)	K Geometric mean (ft/day)
MW-16-02 Slug In	85.8	NA	NA	Not a good match, use slug out test	NA
MW-16-02 Slug Out	85.8	4.2E-04	1.2	4.2E-04	1.2

MW-16-10 Slug In	135.3	3.6E-05	0.10	3.6E-05	0.10
MW-16-10 Slug Out	135.3	3.7E-05	0.10		
MW-16-11A Slug In	127.3	6.1E-05	0.17	6.3E-05	0.18
MW-16-11A Slug Out	127.3	6.5E-05	0.18		

K = Hydraulic Conductivity

NA = Not applicable

WC = water column height in well

A 5' long by 1" diameter slug was utilized to complete slug tests in these wells in September 2021.

SOIL BORING NO. 28

BECHTEL Belle River

DESCRIPTION

Cinders, fill  
Sandy topsoil  
Soft, brown & gray, silty Clay (CH)  
trace fine sand, high plasticity  
Stiff, brown, some fine sand

Very soft to soft, gray, silty Clay (CH-CL)

Firm, gray, sandy clay layer

Gray, silty Clay (CL) medium plasticity, 20% fine to coarse sand

Stiff, dark, gray clayey sand (SC)

Firm to stiff, gray, silty clay (CL), silt lenses  
Hard, some fine sand

Compact, gray, fine sand (SP)

silty fine sand (SM) 15% nonplastic fines

Compact, gray, very fine to coarse sand (SW)

Silty sand (SM) 15% nonplastic fines

Bottom of hole - Elevation - 451.4  
- Depth - 135.0 ft

This hole stopped at 135.0 ft. due to gas.

With casing at 110.0' no gas. Casing pulled to 57.0'. No gas. Pulled to 50.0', gas bubbling in hole. Capped hole and left for 48 hours. After 48 hours no gas (pocket only)

2-8-74 No gas  
2-11-74 Gas  
2-11-74 Pulled to 50.0', capped  
2-11-74 1400 hours removed cap (no gas)

82.5' - 107.0' used Gel to keep open

For Water Table Information consult Section 4.1.3.

Hole backfilled with Quik-Gel in soil
